# INDEX TO MECHANICAL ENGINEERING

Volume 42, January to December 1920

For Engineering Survey see Separate Index, page IX

D, denotes discussion; C, correspondence; page numbers in parentheses are those of Section Two

<b>A</b>	Appraisal and valuation of properties	549	BARTLETT, HENRY B., necrology	461	
Aeronautic instruments	263	Arch-fused metal, properties of the	567	BEACH, COL. LANSING H., new chief of engineer corps	135
Aeronautic Section organizes	(136)	Arm-welding process, metallic-electrode	572	BEAN, W. L., Steam vs. electric locomotives (D)	687
petition granted	(162)	Armor-plate and gun-forging plant of U. S. Navy	657	BEAUBREUX, R., Steam vs. electric locomotives (D)	688
under way	(153)	ARMSTRONG, A. H., Steam vs. electric locomotives—the electric side	685	Belgium, German defenses on the coast of	319
Aerodynamics in the U. S.	192	Asbestos, sheet, value of on hot pipes 69 (C)	188	Beltung, steel, an experimental investigation of	369
recent development of, in America	253	ASHWORTH, DANIEL, necrology	(46)	BENEDICT, B. W., The training of engineering students in industrial management	492
Aeroplanes, cruising radius of	364	A S M E. Annual Meeting, 1919	32	BENJAMIN, CHARLES H., The testing of farm tractors	401
rectilinear flight of	268	President's address and reception	32	BENNETT, COOLIDGE JOHNSON, necrology	(80)
Aims and organization report in effect	(43)	Business meeting	33	BENOIT, A. W., Organization and construction of dye houses	673
Resolution by Buffalo Section on recommendations of committee on policy of A. S. M. E.	(7)	Appraisal and valuation session	35	BEXER, OTTO S., Scientific development of the steam locomotive (D)	40
Aircraft standardization, international	651	Industrial situation session	34	BIBBINS, JAMES R., Rational valuation—a comparative study	549
Air flowing into a vacuum, calibration of nozzles for measurement of	607	Machine design session	36	BIBBINS, C. H., Brass and bronze castings	439
flow through small brass tubes	334	Power machinery session	37	BILLINGS, CHARLES ETHAN, necrology and portrait	475
Airplane engines, superchargers for	383	Textile session	39	Birmingham Section	(81, 163)
Air-propeller design, physical basis of	213	Transportation session	40	BISBERRY, ALLAN S., necrology	(114)
AIRWORTH, N. W., Foundations for machinery	671	Machine shop session	41	BLANDFORD, ALLEN H., Turbo-compressor calculations	151
Akron, A. S. M. E. meeting at	203	General session	42	Boiler Code Committee, work of	48, 126, 187, 248, 302, 417, 472, 531, 703
Engineering Society of, holds first annual dinner	(100)	A S M E. brief history of and notes on first annual meeting of	(150)	data sheets of the interpretations of, promulgation by the American Union Boiler Law Society	704
Engineering Society of, meeting	(135, 155)	A S M E. Fortieth Anniversary celebrated on November 5	(149)	Boiler tubes, constitution and properties of	603
Section approved by Council	(99)	A S M E. Officers for 1921 announced	(152)	Boilers of locomotives, code for	187
Section meeting	(163)	A S M E. recommendations on the policy of	(7)	Bolts and nuts, tight-fitting threads for	222
ALEXANDER, H., Profit sharing in industry (D)	35	A S M E. representatives on American Engineering Council	(135)	Book notes and reviews	81, 143, 205, 261, 317, 368, 485, 548, 601, 655, 726
ALFORD, L. P., Profit sharing in industry (D)	35	A S M E. Spring Meeting, 1920	386	Book, the new fall	(10, 25, 47, 63, 91, 101, 163)
Section on industrial unrest	36	Business meeting	387	BOVIE, T. A., Gray-iron castings (D)	440
ALLEN, JOHN ROBERTS, biographical sketch of, necrology and portrait	(711)	Appraisal and valuation session	387	BOWER, W. S., Control in industry (D)	35
ALLEN, LESLIE H., The financial problems of industrial housing	346	Local session	391	BRASHEAR, JOHN ALFRED, necrology	311
Alloyed aluminum as an engineering material	495	Aeronautic session	395	Resolutions on the death of	(98)
Alloy steels in the automotive industry, some applications of	501	Castings session	393	Brass and bronze castings	435
steel, some commercial heat treatments for	506	Scientific session	395	BUCKENRIDGE, L. P., E. F. C., water-tube boiler for wood ships (D)	37
ALTA, LUCAS N., necrology	456	Power session	397	Bridgeport Section (See Connecticut Section)	(115)
Altitude flight of Major R. W. Schroeder	245	Tulsa visit	398	BRITAIN, GREAT, National Physical Laboratory of British research associations	638
Aluminum, alloyed, as an engineering material	495	A S M E. Spring Meeting at St. Louis	399	BROCK, CLYDE E., Pipe lines for transporting natural gas	445
castings	427	Aspirators for sterilizing water, design of	562	BROOZE and brass castings	435
Amendments, constitutional (by M. L. Cooke and F. J. Miller), mailed to membership	(137)	Association of iron and steel engineers, annual meeting of	652	BROWN, STEPHEN P., BROWN, necrology	(14)
American aerodynamics and McCook Field	441	Atlanta Section	(10, 25, 47, 62, 91, 101, 163)	B. T. U., proposed symbol for (C)	214
American Chemical Society, meeting of	653	Australia, development of labor situation in	421	Buffalo, Engineering Society of, meeting	249
American Drop Forge Association, meeting of	546	Austrian engineers appeal for help	593	Buffalo Section, meetings	(10, 25, 48, 101, 155)
American Electrochemical Society, meeting	728	Autogenous welding of boilers and pressure vessels	594	Bulletin on Society affairs, special	362
American Engineering Council, A. S. M. E. representatives on	(135)	Automobile show, New York, 1920	70	Bureau of Standards, technical work at	135
Executive Board of, meeting	723	Automobiles, passenger, economy of at various speeds (C)	705	BURTON, MARION L., inaugurated as president of University of Michigan	(71)
first meeting of	724	Automotive industry, some applications of alloy steels in the	501	By-laws and rules, changes in constitution and By-product producer gas, why not? editorial	708
American Engineering Standards Committee actively engaged in organizing standardization work	193	A. V. E. L. L. E. M. O. R. T. Causes of industrial unrest and the remedy (D)	36		
American Foundrymen's Association, meeting	724	Averages, the correct statement of (C)	189		
American Gear Manufacturers' Association, meeting	366	Aviation, the future of	28		
American Institute of Electrical Engineers, meeting	258	Awards to be developed	(41)		
New York Section of meeting	74				
American Institute of Mining and Metallurgical Engineers, annual report of	259				
meeting of	258				
American Iron and Steel Institute, meeting of	484				
American Railway Engineering Association joins Engineering Council	306				
meeting of	315				
American Society for Steel Treating, annual convention of	652				
American Society for Testing Materials, meeting of	546				
American Society of Heating and Ventilating Engineers, meeting	181				
Among the local sections (See Sections)					
ANDERSON, ROBERT J., Brass and bronze castings (D)	440				
Annals, the September issue of, noteworthy papers on labor, management and production in	594				
Annual Meeting, A. S. M. E., 1920, plans for, assure phenomenal success	646				
tentative program of	647				
note on	(133)				
Annual meetings, on housing the	6				

<b>B</b>	BAKER, CHARLES WHITING, Extending ocean navigation to the Great Lakes (editorial)	592	CALDERWOOD, J. P., A. Mack, J. J. HOBBS, L. S. POTTER, A. A., The best insulating value of brick and bit brick (C)	624		
BAKER, WILLIAM M., necrology and portrait	(46)	BAKER, GEORGE M., Industrial situation in relation to present conditions (D)	30, 31	CALDWELL, F. W., and FALES, E. N., Physical basis of air-propeller design	213	
BALTIMORE SECTION, (10, 47, 62, 81, 91, 155, 163)	(61)	BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Calibration of nozzles for measurement of air flow	607	
BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Ball bearings, effect of radial plating on life of (C)	704	CAMMEN, LEON, McCook field and American aerodynamics	41	
BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Ball bearings, effect of radial plating on life of (C)	704	Candidates for membership	(19, 35, 58, 71, 129, 143, 159)	170
BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Ball bearings, effect of radial plating on life of (C)	704	Carbonization, effect of depth of copper plating on	565	
BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Ball bearings, effect of radial plating on life of (C)	704	CARROLLT, JOSEPH A., necrology	(156)	
BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Ball bearings, effect of radial plating on life of (C)	704	CARMAN, President-elect E. N., carries greetings from Canadian engineering societies	(153)	
BALB, BENJAMIN, Effect of radial plating on life of (C)	704	Ball bearings, effect of radial plating on life of (C)	704	CARMAN, E. S., Federated American Engineering Societies, editorial	426	

Dallas Technical Club, of John F. A. S. E.	480
Dallas, Texas, joint meeting of Mid-continent and Houston sections of	16(2)
DAVIS, A. P., remarks by, at Fortieth Anniversary A. S. M. E. meeting	78
DAY, V. S. The value of steel asbestos on hot pipes, C.	189
DE BAUTFE, WILLIAM L. Calibration of nozzles for measurement of air flowing into a vacuum	607
DEBROS, COL. E. A. The future of aviation	78
DE FREMINVILLE, CHARLES, elected to honorary membership in the A. S. M. E.	78
Reliability of materials and mechanism of fracture	207
DeLaMater collection presented to A. S. M. E.	707
Design of air propeller physical basis of	213
of ore fleet for upper Mississippi	319
of hoisting drums, rational	635
Determination of fiber stress caused by force bits (C.)	573
Detroit Engineering Society, meeting of (A. S. M. E.)	135, 154
Detroit section meetings	28, 63, 164
Development problems, civil engineers discuss	192
DICKIE, A. J. Fuel and power conservation on the Pacific coast (special correspondence)	107
DICKSON, WILLIAM B., address by, at A. S. M. E. Fortieth Anniversary	713
Die castings	435
Diesel-electric drive for ships	255
Diesel engine, opposed-piston	343
Investigation of, on wet surfaces	230
Domestic service, efficiency of natural gas used in	287
Dredging pump, of novel construction	1
Drives, worm, for rear-axle trucks, tests on	613
Use of, in dredging	382
Dye houses, organization and construction of	673

E	
EMERHART, R. F. Efficiency of natural gas used in domestic service	287
Earthquake, self-supporting chimneys to withstand	157
Eastern New York Section meetings	(25, 48, 81, 164)
EMERHART, HENRY J. Thread forms for worms	42
Employment (D)	12
Economic loss caused by rust (C)	12
Economy of passenger automobiles at various speeds (C)	705
Editorial associates on MECHANICAL ENGINEER	157
Education, A. S. M. E. Committee on	352
Education, industrial, a great work possible in	(134)
EDWARDS, SAMUEL H. necrology	592
Efficiency of natural gas used in domestic service	(140)
ELKHART, CHARLES, necrology	287
Electification of officers for 1921..	(14)
Electric-arc welding of steel properties of the	(24)
are forced metal	567
Electric power for Holyoke, Mass.	70
power supply of southern textile mills	161
side, steam vs. electric locomotives	684, 685
steam locomotives	680
welding, notes on	567
Electrodeposition of iron	416
Elevators, standardization of	747
ELMER, C. F. Price levels in relation to value	553
ELKHART, H. Wage payers (D)	35
ENRICH, W. L. R. Edison Medal presented to	(111)
portrait of	(111)
ENRICH, FREDERICK LYNCOLE, necrology	(80)
Employment, representation in management of industry	133
Employment Bulletin	(15, 29, 48, 66, 82, 93, 103, 113, 125, 141, 156, 166)
Employment Bureau of Engineering Societies, note on	113
completes successful year	66
Engineer and the woodworking industry	448
Engineering Council, specialized curricula in	127
Engineering Council, committee of, on licensing of engineers	127
report of committee on classification and	
recognition of engineers	138
activities for 1919, a review of	(41)
resolves its endorsement to F. A. E. S.	480
Engineering division of National Research Council issues report	610
Engineering Foundation, endowment of	450
report, progress in research	137
seek large endowment	363, 398
Engineering Index in all issues	19
annual volume of to be alphabetically arranged	69
annual volume to be issued May 15	253
for 1919 not issued	763
issued in new form	69

Engineering Institute of Canada meeting	20
Engineering Progress, a new periodical . . .	30
Engineering research . . . . .	50, 108, 181
245, 300, 349, 414, 470, 528, 588, 638	700
Engineering societies in industry, functions of	128
Engineering societies, news of the . . .	128
74, 202, 238, 315, 366, 483, 528, 600, 652, 724	190
first step toward federation of . . .	190
Engineering Society of Western Massachusetts meeting . . . . .	74, 202, 250
Engineering society, ten ways to kill a branch of an . . .	128
Engineering Survey (See separate index)	128
Engineering, what is it? . . . . .	128
Engineers' relation to public questions . . .	366
salary and present conditions . . .	128
ENGLISH, WILLIAM T., necrology . . . . .	128
ENNIS, WILLIAM D., Cao engineering students . . .	128
will bring broad conception of production and management (C) . . . . .	640
Discussion of the horsepower of resistance (C) . . . . .	120
ERIKSSON, JOHN, engineers honor memory of . . .	7
British air propeller design . . . . .	210
Fiber Section meetings . . . . .	48, 81
ESCHMOLZ, O. H. Metallic electrode arc-welding process . . . . .	57
Ethics and the engineering profession (secretary's letter) . . . . .	113
Ethics, code of, comments on (C) . . . . .	120
favoring printing in shape for framing report of special committee on . . .	120
restated . . . . .	120
Executive Board of American Engineering Council, meeting of . . . . .	723
Executive departments of Federal Government, Congress to study reorganization of . . .	366
Experimental investigation of steel belting . . .	31

## A Dredging Pump of Novel Construction

By WALTER J. WHITE,<sup>1</sup> NEW ORLEANS, LA.

THE port of New Orleans has long been denied its natural growth by restrictions imposed by the civil code of the state of Louisiana, which declares that the banks of all navigable rivers are public property and as such cannot be sold nor used for factory sites, shipyards, or other industrial enterprises. Attempts have been made to overcome this industrial handicap by proposals to build a navigable canal which would not be subject to the restrictions just enumerated. Some fifteen years ago Mr. Walter Parker proposed that such a waterway be built connecting the Mississippi River with Lake Pontchartrain, but the task was not undertaken until shortly before the war.

It is not the purpose of this paper, however, to deal with the history of this canal nor to present the many industrial advantages which its creation will bring to the port of New Orleans, but rather to present some of the outstanding engineering features incident to the completion of the work.

It may be of interest to note in passing, that in spite of the prevalent belief that the civil code has been a handicap to the general industrial development of New Orleans, even if there were no law standing in the way, manufacturing plants located upon the Mississippi would be exposed to many dangers occasioned by the encroachment of the river. Furthermore, any manufacturing plant due to the great range of level of the river would be burdened with the cost and inconveniences of loading and unloading of water craft and such fact would serve to make impracticable the operation of the plant. It is also generally conceded by experts in shipbuilding that operations of that kind could not be maintained on the banks of the river with any hope of success. It is of course obvious that an inner-harbor navigation canal (controlled by locks) would be entirely suitable for all such purposes.

During the construction of the canal the very unusual character of the dredged material necessitated a complete change in the construction of the dredge pumps, and because the en-

gineering features are particularly interesting, it is to this phase of the work that the writer wishes to direct attention; but before proceeding to examine the methods employed, a brief description of the canal itself will undoubtedly be of interest.

The surface elevation of that part of the city of New Orleans in which the canal is located is the same as mean gulf level. Occasional high tides, due to storms, occur when the water rises to an elevation of from three to five feet higher than the ground surface. It was therefore desirable that the dredge excavation

be handled in such a way that the greatest benefit would be secured from the disposal of the material. This was accomplished by depositing the dredged material so as to form as nearly as practicable a continuous fill, which thus serves as a levee along both banks of the canal and which prevents any possibility of overflow during storm tides. The dredge excavation furthermore provides high, well-drained sites for shipyards and other industries. The length of the Inner Harbor-Navigation Canal from deep water in the Mississippi River to the 14-ft. contour in Lake Pontchartrain is 31,800 ft. The completed project is to have a clear channel width of 150 ft. on the bottom with a depth

FIG. 4 THE DREDGE *Captain Huston*, USED IN THE EXCAVATION OF THE NEW ORLEANS INNER-HARBOR NAVIGATION CANAL

of 30 ft. below low water. In the development of shipyards and other industrial sites no encroachment on the channel width will be allowed, such locations being provided with launching basin, slips, piers, etc.

While it is true that the Mississippi River and Lake Pontchartrain will be connected, it is believed that the use of the word canal is misleading and very likely to be misunderstood. It should be remembered that Lake Pontchartrain is a shallow body of water when compared with the depth of 30 ft. in the inner harbor. The present plan contemplates the construction of an inner harbor, or basin having a constant level and connected with the deep-water channel of the Mississippi River, entrance from the river channel to the inner harbor being by means of one lock. After the harbor feature has been considerably developed, it is quite probable that extensive dredging operation will be undertaken to establish a deep-water channel from the north end through Lake Pontchartrain and Mississippi Sound to the Gulf,

<sup>1</sup>Supt. of Dredging, Board of Commissioners, Port of New Orleans. Assoc. Mem. Am. Soc. M. E.

Abstract of a paper presented at the Annual Meeting, New York, December 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

FIG. 2 VIEW OF CANAL SITE LOOKING SOUTH FROM THE RAILROAD

thereby justifying, in the fullest sense, the name Inner Harbor Navigation Canal—an *Inner Harbor* having a constant level and a *Canal* connecting deep water in the Mississippi River with deep water through Lake Pontchartrain to the Gulf.

During the construction of the canal, traffic had to be maintained over railroads, electric-car lines, and highways which crossed the line of the Inner Harbor. This feature and the necessity of utilizing the excavated material in levees and fills along the banks, and also the requirement that all excavated material be deposited well back from the edge of the bank, prohibited the use of dipper dredges or other types of dredges which dispose of material by means of sews or by depositing along edge of cut.

While planning methods by which this dredging could be done economically, and at the same time rapidly, several test pits were excavated which confirmed the belief that about 80 per cent of the area to be excavated was underlaid with large cypress stumps which at some time in the past had either subsided or had been covered by deposit from overflow. In addition to the submerged

stumps there was a heavy surface growth of cypress and other timber from Station No. 88 to Station No. 221. The topography of this country is best shown by Figs. 2 and 3. After clearing the standing timber from the area to be dredged tentative efforts were made to remove all stumps by shooting and grubbing, but it was found that this would greatly increase the cost of the work. During the progress of the work very little manual labor was expended on stumps and roots, although it was found to be advantageous to blast some of the larger surface stumps.

Notwithstanding the great number and character of stumps and roots, as evidenced by Fig. 4, it was decided for the reasons mentioned that the work could best be done by hydraulic pipe-line dredges of the cutter type and contractors were asked to submit bids on the work. Due to the difficulties mentioned, however, contract prices could not be secured and arrangements were therefore made to charter dredges, the Board of Port Commissioners accepting all responsibility for output. Four 20-in. dredges, and one 22-in. dredge, the *Texas*, were accordingly secured and work was commenced on May 15, 1918. Fig. 1

FIG. 3 VIEW OF CANAL AFTER EXCAVATION

shows one of these dredges, the *Captain Huston*. The dredges were powerful machines of good design in all respects, but it was fully realized that much trouble was to be expected on account of stumps and roots.

By utilizing Bayou Bienvenue four of the dredges were brought in to a point on the canal near Station No. 88, where one was placed in operation headed toward Lake Ponchartrain and three were started toward the Mississippi River; one dredge was also started south from Lake Ponchartrain. On account of large areas in suction and discharge pipes and pump, the 22-in. dredge *Texas* was placed in the most difficult section. After allowing a reasonable time for dredge and crew to become adjusted to conditions, it became evident that progress would be slow and the work would be expensive, due entirely to delays and decreased capacity occasioned by stumps and roots clogging pump throat and suction. The soil itself was easily handled by a hydraulic dredge and the pipe-line conditions were not difficult, but the amount and character of roots encountered and later successfully handled is beyond description. Fig. 5 shows the character of the material actually pumped through the dredge *Texas*. It was thought that the solution of this difficulty would be found in a pump impeller designed with large and easy passage areas and having no projecting webs on vanes or hub. The writer learned that Mr. A. B. Wood, mechanical engineer for the Sewerage and Water Board of New Orleans, had designed and patented a centrifugal-pump impeller for handling sewage containing trash. An impeller for a 12-in. pump was inspected, and while none had heretofore been used on dredges of the cutter type it was believed that the root problem was solved and Mr. Wood was engaged to design an impeller for the 22-in. dredge *Texas*. All costs in connection with the manufacture of the impeller were to be borne by the Board of Port Commissioners regardless of whether or not it proved a success.

From the first the results obtained with the new impeller were remarkable, the increase in output being between two and three hundred per cent. The increased yardage excavated by the dredge *Texas* is shown by the following comparative statement, covering thirty days' operation immediately before and immediately after

FIG. 4 CHARACTER OF EXCAVATION ENCOUNTERED

substituting Mr. Wood's impeller for the old type:

	Old Impeller	New Impeller
Excavating, hours .....	482.43	394.00
Clogged suction delay, hours.....	130.75	71.50
All other delay <sup>1</sup> , hours.....	106.82	254.50
Advance, feet .....	873	2,901
Excavated material, cubic yards.....	73,472	175,460
Average yardage per excavating hour.....	152	445

The operation and output of the 20-in. dredges *Captain Huston* and *Dixie* was very greatly facilitated and increased by certain modifications made in pump casings and impellers. Area in pump throat was increased by changing the shape of the throat ring and fitting a new piece of suction pipe. As previously mentioned, it was recognized that in order to secure maximum output in material of this character, it would be necessary to provide as large passages through pump and impeller as possible, and it was therefore determined that two-thirds of each alternate vane should be cut out of the impellers in these dredges, as shown in

Fig. 6 and 7. The outer one-third of the vanes was left to preserve structural strength, but after observing the performance of the pumps it is the opinion of the writer that every alternate vane could have been entirely removed.

During the first three days that the dredge *Captain Huston* was in operation and prior to making alterations to the pump the yardage output of the dredge was practically nothing. This was due to the fact that the pump-suction throat was continuously clogged with stringy roots and stumps, which it was impossible for the pump to handle. Conditions could not have been worse and it was felt that any method whereby the pump throat and impeller could be opened up would result in an increased output. It is admitted that some uneasiness was felt as to how these alterations might effect the performance of the pumps, but results have more than justified what at first seemed to be a drastic and

FIG. 5 STUMPS AND ROOTS HANDLED AND ACTUALLY PUMPED BY THE DREDGE *Texas*

<sup>1</sup>The large number of delay hours after installation of new impeller was due to time lost cleaning boilers and raising a sunken fuel barge. For the period covered in the tabulation it will be seen that although the installation of new impeller decreased the number of excavating hours, the average advance in yardage was much greater. From observation of the dredge in operation it was seen that the ability of the impeller to pass stumps and roots insured the maintenance of a satisfactory output.

hazardous measure. Pump and engine tests, typical curves of which are shown in Fig. 8, have shown that these alterations did not effect the capacity or efficiency of the pump, other than by greatly facilitating the passage of roots, etc., through the pump. While the writer understands that radical alterations should not be made without careful consideration, it is undoubtedly true that the performance of a dredge is to be judged largely, if not solely, by the unit cost of output, and where for any reason output is

The impeller designed for the 22-in. dredge *Texas* was of same diameter (80 in.) as that of the old impeller, but it had two instead of four vanes. An examination of Figs. 9 and 10 will show that, due to the peculiar shape of vane, the lodging or collection of roots or other material is made difficult, if not impossible, every encouragement being given by shape of vane and throat of impeller to the continuous flow of water containing irregular shape roots or other objects. The writer does not wish to convey

FIG. 7 DETAILS OF PUMP ON DREDGE *Captain Huston* SHOWING THE MODIFIED THROAT AND IMPELLER

not ~~also~~ secured any modifications of plant are justified, provided that the unit cost of output is controlled. In this particular instance there was involved the difference between failure and success. Assuming the same general character of excavation, a further modification along the lines indicated would, it is believed, result in a further increase in output.

the impression, however, that all of the large cypress stumps and roots were cut up by the cutters and handled through a 20- or 22-in. dredging pump. While suction ladders were built for heavy service and cutters were of good design and powerful, a great many of the stumps were undercut and allowed to sink to the bottom, where they were deposited below grade.

In general the operation and maintenance of the dredges followed the usual procedure for dredges of this type, and it is not believed that any novel feature other than in connection with modification of pump design can be presented. The 22-in. dredge *Texas* was equipped to use ball joints as connections between sections of pontoon pipe, and it is believed that the passage of roots was made easier than if rubber sleeves had been used.

Pump impellers having two, three, four, six, and seven vanes and varying in diameter from 68 in. to 96 in. were used in the different dredges engaged on this work. While it is the intention to present methods and actual results secured rather than to discuss the design and performance of centrifugal pumps and impellers, it is thought that some comparative observations made of the different pumps will be interesting. Tests to determine certain centrifugal dredge-pump characteristics while pumping water were carefully made. The results of these tests are given in Tables 1 and 2. Observers were selected and were rehearsed several times to make sure that they understood just what was required of them. All practicable precautions were taken so that accurate results would be secured. Readings were recorded as observed, the object being to eliminate any intention to interpret or analyze readings while test was in progress. A study of the readings does not reveal any wide range in any set of readings for a given condition. All the figures in Table 1 are a mean of a number of readings and the writer has confidence in the correctness of all observation and computations, and it is believed that the data presented will be of value in analyzing and studying the design and performance of centrifugal dredging pumps. At the time tests were made, the dredges were in good operating condition, but no special preparation of machinery was made. All of the pumps tested were of the single suction type and all impellers, with one exception, were shrouded on both sides. The pumps were directly connected to vertical triple-expansion engines.

Upon the completion of the tests made on the dredges *Captain Huston* and *Dixie*, both of which were equipped with pumps

curved in the direction of rotation. The results were surprising and are shown in detail in Table 1 and the curves of Figs. 12 and 13. So far as the operation of the dredge was concerned, both while pumping water and also while dredging, there was nothing

FIG. 9 REAR VIEW OF TWO-VANED IMPELLER DESIGNED BY A. B. WOOD

to indicate to the closest observer that the pump was not assembled in the usual manner. After completion of tests it was found by comparison that there was a 10 per cent loss of

FIG. 8 CURVES OF DREDGE *Texas* EQUIPPED WITH IMPELLER DESIGNED BY A. B. WOOD

having modified propellers, it was decided to test the pumps of the dredge *Pelican*, which was fitted with an open impeller. This pump, shown in Fig. 11, was tested with impeller in the pump in the normal manner with the vanes curved backward and also with the impeller reversed,<sup>1</sup> i.e., with the vanes

FIG. 10 VIEW SHOWING THE LARGE PASSAGeways OF THE IMPELLER DESIGNED BY A. B. WOOD

efficiency due to increased consumption of power with the reversed impeller. As a matter of interest it might be stated that the dredge *Pelican* was operated from June 1 to June 14, 1919, with the reversed impeller, nothing unusual being noticed in operation and no diminution in yardage being apparent.

<sup>1</sup>In *Trans. Am. Soc. C.E.* vol. 50, page 505, Oct. 1905, Colonel C. W. Sturtevant, *Mem. Am. Soc. C.E.*, mentions a centrifugal pump having been operated with impeller vanes curved forward instead of backward.

In the tests of dredges *Texas* and *Captain Huston* the quantity of water discharged by the pump was measured by pitot tube and venturi meter. While testing the dredge *Captain Huston* the pitot tube was bent and was not used in the tests of the other dredges. During tests the venturi meter was located just astern of the dredge in a straight section of pipe, where it would not be influenced by elbows. Suitable arrangements were made so that the discharge pipe could be throttled, or closed off entirely, and in this way a variation in head and quantity was created. Piezo-meters were  $\frac{1}{4}$ -in. tee-handled pet cocks, which were screwed into

which reference has already been made; one 20-in. dredge was chartered at a monthly rate for the bare dredge, all operating and maintenance costs being borne by the Board; and two 20-in. and one 22-in. dredges were chartered by the Board at a rate to include all operating and maintenance charges except fuel and shore pipe line, which were borne by the Board. In securing dredges for this work it was necessary to tow them to New Orleans from more or less distant points, two having been brought from Havana, Cuba, the Board assuming all towing charges and paying one-half the charter rate while dredges were in transit. A

the pipe. Indicators were not calibrated, but are believed to have been in excellent condition. Cards were taken simultaneously on the three engine cylinders. It was unfortunate that during the drop in pressure test made on dredge *Dirie* it was impossible to obtain comparable peripheral speeds due to valve of intermediate cylinder being improperly set.

From May 17, 1918, to August 1, 1919, there were employed in the construction of the Inner Harbor-Navigation Canal four 20-in. dredges and one 22 in. dredge. One of the 20-in. dredges was owned and operated by the Board of Port Commissioners, to

careful record of costs was kept and the total yardages by months and the total and the unit costs of the same will be found in Table 3, page 80. These costs are divided under three headings:

#### ARBITRARY

Cost of towing to and from New Orleans

One-half rental paid while in transit

Cost of 477,193 cu. yd. of preliminary and auxiliary dredging

Cost of design and manufacture of two-vane impeller for 22-in. dredge

\* Readings of suction gage incorrect because of whirl set up in pipe by pump impeller.

† Suction readings incorrect due either to pet cock being throttled down too much or getting temporarily choked up.

DISCHARGE-PIPE-LINE CONDITIONS FOR TESTS OF DREDGING PUMPS  
GIVEN IN TABLE 1

*Texas:* Tests 1 and 4, 8-in. valve on end of discharge pipe wide open. Tests 2 and 5, 8-in. valve on end of discharge pipe cut off. Test 3, pipe line 570 ft. pontoon and shore pipe.

*Captain Huston:* Test 1, Pipe full opening. Test 2, Iron plate bolted on discharge pipe. Tests 3, 7, and 8, 8-in. valve on end of discharge pipe wide open. Tests 4 and 9, 8-in. valve on end of discharge pipe cut off. Tests 5 and 6, Pipe line 3538 ft. pontoon and shore line.

*Dixie:* Test 1, Pipe full opening. Test 2, Wooden piece bolted on discharge pipe. Tests 3, 5, and 6, Pipe line 1583 ft. pontoon and shore pipe. Test 4, 2 pieces of wood bolted on end of discharge pipe. Test 7, Iron plate bolted on end of discharge pipe. Tests 8 and 11, 8-in. valve on end of discharge pipe wide open. Tests 9 and 12, 8-in. valve on end of discharge pipe partly closed. Tests 10 and 13, 8-in. valve on end of discharge pipe cut off.

*Pelican:* Tests 1, 2, and 3, Pipe full opening. Tests 4 and 15, 8-in. valve on end of discharge pipe cut off. Tests 5 and 10, Wooden piece bolted on end of discharge pipe. Tests 6 and 11, 3 wooden pieces bolted on end of discharge pipe. Tests 7 and 14, 8-in. valve on end of discharge pipe partly closed. Tests 8, 12 and 13, 8-in. valve on end of discharge pipe wide open. Test 9, 2 wooden pieces bolted on end of discharge pipe.

*Pelican (with reversed runner):* Tests 1, 2, and 3, Pipe full opening. Test 4, Wooden piece bolted on end of discharge pipe. Tests 5 and 12, 3 wooden pieces bolted on end of discharge pipe. Tests 8, 14, 17, 18 and 19, 8-in. valve on end of discharge pipe cut off. Tests 7 and 8, 8-in. valve on end of discharge pipe partly closed. Tests 9 and 11, 2 wooden pieces bolted on end of discharge pipe.

In all cases where length of discharge pipe is not given the length was less than 100 ft. from the stern of dredge. In general, it should be stated that the figures in Table 1 are a mean of a number of readings recorded during tests, which explains why the figures are worked out to two decimal places. The venturi meter had an inlet diameter of 22 5/16 in. and a throat diameter of 18 in. For readings at cut off, the elevation of water at rest in suction pipe was taken as suction head and for other readings of low quantity the suction head was taken from loss pressure curve plotted from high quantity readings.

# Thermal Conductivity of Insulating Materials

By T. S. TAYLOR,<sup>1</sup> EAST PITTSBURGH, PA.

Despite the fact that numerous thermal-conductivity measurements have been made, but very few data are available for such materials as are used in the construction of electrical machinery. To further investigate this field the author accordingly conducted a series of tests based upon two methods, both of which are explained in detail in this paper. The results obtained are tabulated in the complete paper for such materials as fish paper, fuller board, cambric, mica tape, various kinds of woods, asbestos, plate glass, sheet steel, wool felt, etc., and a selection covering various miscellaneous materials is given in the present abstract.

**A**LTHOUGH numerous experimenters have been interested in making thermal-conductivity measurements, but very few data are available for such materials as are used in the construction of electrical machinery. The most important work on such insulating materials thus far available was done by Symons and Walker,<sup>2</sup> but the materials tested by these authors were special and consequently the values obtained cannot be taken as applicable to similar materials used in the construction of electrical machinery in this country. The investigations herein described were therefore undertaken to obtain values of the thermal conductivity of insulating and other materials, the values of which are of direct interest to those concerned with the heat problem in electrical apparatus. Results have also been obtained for numerous other materials of general interest.

## THE NORTHRUP THERMAL BRIDGE

As a preliminary step it seemed worth while to try the "Thermal Bridge" method suggested by Prof. E. F. Northrup.<sup>1</sup> The bridge used is shown in Fig. 1. It consisted of two soapstone cylinders each 4½ in. in diameter, one being 8½ in. long and the other 3 in. long. Each cylinder consisted of an inner core 1½ in. in diameter surrounded by a concentric cylinder having a wall thickness of 1½ in. The two faces along *MN* separating the two parts of the apparatus were ground so as to fit very closely. A spiral groove was cut in the top of the longer cylinder *E* and a heater wire placed in this groove. Small holes, 1, 2, 3, etc., were drilled at right angles to the axis of the cylinders through the outer wall and into the central core as indicated. Copper-constantan thermocouples made of 0.005-in. wire were inserted in these holes for the purpose of determining the temperature gradient along the cylinders. The lower part of the apparatus *F* was placed on a brass box which served as a cold-temperature reservoir when kept filled with water and ice or when the water was kept circulating through it. The heat generated at the top would flow down the core and outer wall through the junction *MN* to the reservoir. The purpose of the core and surrounding wall was to insure a uniform flow of heat through the core. Felt was placed around the outer cylinder to further prevent undue loss of heat from the surface of the apparatus.

If the distance from thermocouple 1 to thermocouple 5 is made the same as that from 2 to 8, and the conditions are such that a uniform temperature drop exists along the core, the thermal conductivity of a material placed in  $MN$  can be determined in terms of soapstone. First suppose the above conditions to exist when there is no specimen in  $MN$ . Then the temperature drop will be uniform along the apparatus, as can be tested by the thermocouples. When a sample is inserted in  $MN$  and the temperatures of 1, 5, 2 and 8 are measured, the drop between 2 and

8 exceeds that from 1 to 5 by an amount equal to the drop through the sample. The soapstone equivalent of the sample is then readily calculated from the temperature drop through the sample and the drop per unit length along the soapstone.

[In the actual experiment, described by the author in his complete paper, the procedure was slightly different from that outlined above, from the fact that the distance from thermocouple 1 to 5 was not exactly the same as from 2 to 8. The use of the thermal bridge, however, proved to be unsuited to the work, for a series of tests gave results that varied considerably. Another method was therefore employed in which use was made of a "thermal meter." A description of this method follows.—EDITOR.]

### THE "THERMAL METER"

A sketch of the "thermal meter" used is shown in Fig. 2. It consisted essentially of an electric heater  $H$  constituting two hot

FIG. 1 DIAGRAMMATIC SKETCH OF THE NORTHRUP THERMAL BRIDGE

quiperature surfaces or sources of heat and two cooling chambers  $E$ ,  $E$  (one on either side of the heater) or cold constant-temperature surfaces. The heat generated in  $H$  passed laterally through the samples  $I$ ,  $I$ , of a given material to the cold reservoirs  $E$ ,  $E$ . The heater was made from two disks of soapstone 9 in. in diameter and  $\frac{3}{8}$  in. thick. Each disk had a spiral groove of 3/16-in. pitch cut in one face. A heater wire, No. 21 constantan, was wound and cemented securely in the groove of each disk and then the iron disks were cemented together with the sides containing the heater wire adjacent. The two heating elements in the two disks were joined together at the center by means of a peg in one disk being pushed into the spring contact in the other. Potential leads were brought out from each heating element at points 2 in. from the centers. It was later found that potential leads fastened to the heating elements at the points

Abstract of a paper presented at the annual meeting, New York, December 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

where the wire started in the outer terminals of the spirals served equally well, since the temperature coefficient of resistance of the constantan wire is very small and furthermore the temperature of the heater was constant over its entire face. Extra turns of wire were wound around the outer edge of the heater in order to prevent the loss of the heat generated in the heating element proper through the edge of the heater. After several trials it was found that this procedure gave a heater which in use had a very constant temperature over its two faces, even up to the outer edge.

Two samples of the material to be tested were always used, each being 9 in. in diameter and from 0.1 to 0.75 in. thick, depending upon the nature of the material. One sample was placed on each side of the heater *I, I*, Fig. 2. Extra disks of lagging of the same material of the sample or something else suitable were placed on each side of the sample, as shown by the shaded portions in Fig. 2. This made the ultimate drop at high temperatures less than it otherwise would have been, and likewise gave a wider range of mean temperature. The faces of the cold reservoirs *E, E*, constituting the cold equitemperature surfaces, were made of heavy brass having a diameter of 10 in. The samples, heaters, and cold reservoirs were held securely together by means of bolts extending between these two plates. At first strong spiral springs were used around these connecting bolts to insure uniform pressure, but it was found later that equally satisfactory results could be obtained by merely turning down the nuts on

FIG. 2 DIAGRAMMATIC SKETCH OF THE THERMAL METER

the bolts till the samples, etc., were drawn tightly together. Thermocouples of 5-mm. copper-constantan wire were inserted on each side of the samples *I, I*, under test. Great care was taken in order to insure good contact between the sample and the thermocouple junction. Two couples were placed on each side of a sample, one at the mid-point and another about  $1\frac{1}{2}$  in. from the center. The electromotive force of the couples (the cold junction being always kept at 0 deg. cent.) was measured by means of a thermocouple potentiometer. The current in the heater was likewise measured by the same potentiometer by measuring the drop through a standard resistance placed in series with the heater. The potential drop per unit length of heater wire was also measured by means of the potentiometer. This necessitated placing a high resistance in parallel with the heater and then measuring the potential drop across a small fraction of this. The current was supplied by a storage battery and consequently remained quite steady. The cold equitemperature surfaces *E, E*, were maintained so by having water from the tap circulating through them continuously. The outer edges of the samples and heater were surrounded by felt in order to prevent undue loss of heat from the edges of the heater and samples.

In order to facilitate the work a second apparatus having the same parts as the one described above was constructed. The only difference being that the heater, etc., were of square cross-section. This heater was made of soapstone slabs 12 in. square. The heater wire (No. 21 constantan) was wound back and forth in

parallel slots  $\frac{3}{16}$  in. apart in each of the parts of the heater. This made its construction quite easy. The elements of the two parts of this heater were joined in parallel as its resistance would have been too high for the available voltage had they been in series. The potential leads of this heater were joined at the ends of a wire in a single groove, thus measuring the drop in a 12-in. length of the wire. Four sets of potential leads were inserted (two in each half) and the average of the four potential drops used in calculating the drop per unit length of heater wire. As for the round heater, extra turns of wire were put around its outer edges to insure a uniform temperature source. Great care was taken to have the same amount of resistance in each element of the heater, since they were joined in parallel. The faces of the cooling reservoirs were of cast brass  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. by 1 in., and being heavy they did not buckle when bolted together over the heater and the materials tested. Identical results were obtained with the two pieces of apparatus for a given material.

The samples of the materials tested were usually composed of one or more sheets. Extreme care was taken to eliminate the air between the surfaces of the component sheets as much as possible by the use of vaseline, shellac, carpenter's glue, etc. By the use of such materials the drop between component sheets was made quite negligible or at least of the same order of magnitude as the drop through the same distance in the material itself. This was due to the fact that the thermal conductivity of such materials as glue, etc., when dried differs but little in order of magnitude from that of the sheet materials dealt with. In making up a sample that material was used to make good contact between the components which lent itself most readily to the case in question.

#### RESULTS OBTAINED BY THE THERMAL METER

Table 1 shows a typical set of results for samples made up of 7 sheets of 0.03-in. fuller board, 0.23 in. in thickness. By plotting the values of the mean temperatures as ordinates and the corresponding values of the thermal conductivity *k* as abscissæ it is possible to get a measure of the temperature coefficients of thermal conductivity. The values given in Table 2 if plotted will give a straight line whose equation is

$$k_t = k_0 (1 - at)$$

where  $k_t$  and  $k_0$  are the thermal conductiveness at temperatures  $t$  and 0, respectively, and  $a$  is the temperature coefficient. From the data given the value of  $a$  for this sample is found to be about 0.0030.

In the manner thus outlined thermal-conductivity measurements have been made for a large number of materials. The values obtained are recorded in Table 3 of the complete paper and values pertaining to various miscellaneous materials will be

TABLE 1 THERMAL CONDUCTIVITY OF FULLER BOARD

found in Table 2 of this abstract. The results in both tables are expressed both in calories per cm. per deg. cent. per sec. and in watts per in. per deg. cent. per sec. The values are also given for a definite temperature such as 20 deg. cent. as well as for an average range 20 deg. to 80 deg. The temperature coefficient is also recorded as determined in the previous paragraph. It is to be observed that all samples did not show a temperature coefficient. This is doubtless due to the changing characteristics

of the samples. Thus it is highly possible that the increase in the thermal conductivity due to an increase in temperature is counteracted by a corresponding increase in the thermal resistance due to the change in the surface contacts and likewise increase in air pockets. Besides measuring the thermal conductivity transversely for sheet material, measurements have been made as shown by Table 2 of the longitudinal conductivity along the laminations. The samples for this latter work were prepared for the one apparatus by winding up disks of the material 9 in.

in diameter, and on the other apparatus by cutting the material into strips and then forcing them tightly together in a special press. By cutting the edges of the strips while in the press with glue they might be held together in a square sample and later placed in the apparatus. It is interesting to note that the ratio of the longitudinal to the transverse conductivity is much greater for the mica compounds than for the other insulating materials. This is due to the influence of the mica, whose longitudinal conductivity is so much better than its transverse. The same ratio has its least value for such materials as varnished cambric and black bias cloth. For these materials there is less difference

between the transverse and longitudinal construction than the mica compounds.

Results were also obtained for the transverse thermal conductivity of 0.0172-in. carbon sheet steel and for 0.014-in. silicon sheet steel. The values obtained are slightly greater than those obtained by other observers for similar materials. Attempts were made to detect the change of transverse thermal conductivity of iron stampings with pressure, but the apparatus did not lend itself readily to this since the exact pressure applied could not be determined. Since this work has been done a testing machine has become available and a study will be made in the near future of the influence of pressure on the transverse thermal conductivity of iron stampings, and this work will be reported later. It is interesting to note that the transverse conductivity of iron stampings can be increased some 3 to 4½ times by coating the sheets with asphalt paint before putting them together. Consequently if the punchings in electrical apparatus could be assembled in groups, having a gum or other suitable material between the constituents so as to have better contact, the heat generated could be much more readily conducted away. This will also be investigated when the work on iron stampings is resumed.

## SUMMARY OF RESULTS

Experiments in the thermal conductivity of insulating and other materials have led to the following conclusions:

- The "thermal bridge" recommended by Professor Northrup has not been found satisfactory for determining the thermal conductivity of sheet materials
- Two "thermal meters," one of circular cross-section and the other of square cross-section, have been found entirely reliable for the measurement of the thermal conductivity of sheet and other materials
- By putting vaseline, glycerine, glue, shellac or a similar material on the division between two surfaces the thermal drop due to such division can be largely eliminated. This is particularly true for poor conductors
- The thermal conductivity has been measured for a large number of materials both across and along the laminations. For the poor conductors the ratio of the longitudinal to the transverse conductivity varies from 2 for black bias cloth to 5½ for mica tape
- The temperature coefficient of thermal conductivity has been measured whenever the experimental results justified.
- Of the electrical insulating materials tested, those containing mica have in general the better thermal conductivity
- As a thermal insulator soft pine is the best of the woods tested and is but little inferior to dark-grey felt.
- The transverse conductivity of iron stampings can be increased some three or four times by the insertion of some suitable material between the stampings so as to make better thermal contact. This is for a pressure of about 50 lb. per sq. in. Nothing, however, destroying the electrical insulation could be used. By using something between sheets the ratio of the longitudinal to transverse conductivity could be reduced to 20 to 25 instead of 80 to 100
- In general the thermal conductivity of laminated products can be considerably increased by suitable impregnation so as to get rid of the air film
- Oil-soaking soft fuller board increases its thermal conductivity by about 50 per cent.
- The best thermal insulation for a given thickness should be made up from several thin sheets rather than from a single sheet. This effect is more pronounced the better the conductor.
- Results were obtained for longitudinal conductivity of iron stampings. 0.0172-in. carbon sheet steel is about two and one-half times better than 0.014-in. silicon sheet steel. Carbon sheet steel has a longitudinal thermal conductivity about 80 times the transverse while silicon has but 32 times the transverse.

# Friction and Spreading Forces in Rolling Mills

Description of Apparatus Designed for a Special Series of Investigations to be Made on the Experimental Rolling Mill at the Carnegie Institute of Technology

By W. B. SKINKLE,<sup>1</sup> PITTSBURGH, PA.

In Mechanical Engineering for May, 1919, announcement was made of the decision of the officials of a number of leading steel works and firms building rolling-mill machinery to organize a Bureau of Rolling Mill Research and to install at the Carnegie Institute of Technology, Pittsburgh, for research purposes, an experimental rolling mill. This undertaking on so large and important a scale marks a distinct advance in coöperative research among manufacturers in this country. The present article by the director of the Bureau of Rolling Mill Research outlines the further development of these plans and in particular describes the equipment which has been designed for a special series of investigations on friction losses and spreading forces in rolls and roll housings as met in the actual operation of rolling mills. A feature of this apparatus is the use of what are practically frictionless support cylinders for measuring the forces acting, which provide hydraulic support in combination with the elements of a pressure gage.

THE need of accurate knowledge of the forces acting on rolls and the friction losses on roll necks in different types of rolling mills has prompted the author to respond to the editor's request for an article, with a description of a device soon to be tried out on the experimental mills of the Bureau of Rolling Mill Research at the Carnegie Institute of Technology.

By means of this equipment it is expected that experimental

acting on the rolls; from which the stresses in rolls and housings may be calculated to a far greater degree of accuracy than is at present possible.

The device consists of two hydraulic supporting cylinders marked Cylinder No. 1 and Cylinder No. 2 in Figs. 1 and 2, located in the bottom of the roll-housing window and so arranged that they can easily be removed and replaced by a filler.

The carrier for the bottom roll rests on the plungers of these cylinders in such a manner that the forces acting on the roll neck are recorded by the resulting hydrostatic pressure in these cylinders.

In Fig. 1 is a diagram showing the arrangement of these cylinders and their relation to the rolls. A bloom is shown between the upper and lower rolls with the lower roll carrier and cylinders. The full lines indicate the position of this carrier under static conditions (condition of rest). The conditions existing at the neck of the lower roll are greatly exaggerated for the purpose of illustration.

The total spreading force  $F$ , due to the bloom being pinched between the rolls, will cause a heavy force  $P$  to be applied about as indicated in Figs. 1 and 2. Under static conditions this force would be transmitted from the body to the neck and would be applied to the bearing as indicated by the arrow  $A$  in Fig. 1. Such an application of forces would cause one half the load  $P$

FIG. 1. ARRANGEMENT OF CYLINDERS AND THEIR RELATION TO THE ROLLS

FIG. 2. DIAGRAM OF FORCES EXERTED DURING ROTATION

data will be secured which will give positive, accurate knowledge, not only of the relative values of the various lubricants and bearing metals used on roll necks, but also of the spreading forces

on each bearing to be carried by cylinder No. 1 and the other half by cylinder No. 2.

<sup>1</sup> Director, Bureau of Rolling Mill Research, Carnegie Institute of Technology. Mem. Am. Soc. M. E.

This article was prepared for Blast Furnace and Steel Plant and is here published through the courtesy of that journal and of the author.

<sup>1</sup> It is not the purpose of this article to enter into a discussion of the complicated system of forces acting at the contact surfaces between rolls and bloom. Inasmuch as the rolls are able to move up or down and are restrained from horizontal movements in any direction by the bearings and roll housing, the resultant of all forces acting must be in a vertical direction.

The proportion of the total force  $F$  which is distributed to each neck of the rolls will depend on the location of the pass in the roll body and can readily be figured by the well-known principles of beam reactions.

Where rotation starts, and the bloom is being rolled, the point of contact between roll neck and bearing changes to some other point, the force  $P$  is then applied to the bearing as indicated by the dotted arrow  $B$ , and the lower roll carrier has a tendency to assume a position indicated by the dotted lines, using the roller  $C$  as a fulcrum point; the roller  $D$  lifting off its seat. The position indicated by these dotted lines in Fig. 1 of course is greatly exaggerated for the purpose of illustration. It is vitally important, however, that the bearing be perfectly free to rotate as indicated, and that no forces other than cylinders Nos. 1 and 2 be interposed to prevent this rotating tendency. (In actual practice it is expected that not more than 0.003 in. or 0.004 in. of movement will be obtained on these cylinders between no load and their maximum carrying capacity of 250,000 lb. each.)

When the contact point has moved to a place where it slides

on the lower roll-neck bearing, we have  $-P + NP + MP = 0$ , whence  $NP + MP = P$ . Canceling the  $P$ 's we have

$$N + M = 1$$

This shows that for each increase of over half the total load carried by cylinder No. 1 there is a corresponding decrease in the load carried by cylinder No. 2 and that the sum of the pressures on cylinders Nos. 1 and 2 must be equal to the force  $P$ . This same fact can be shown by taking moments about the point  $x$  where the roll neck applies its load to the bearing. In this case the force  $P$  has no lever arm. Its moment would therefore be zero, and it may be neglected. Taking moments about  $x$  we have

$$+NP(D-d) - MP(D+d) = 0$$

which expands into

$$NP D - NP d - MP D - MP d = 0, \dots \dots [1]$$

Taking moments about  $Y$  the center of the roll neck we have

$$-P d + NP D - MP D = 0, \dots \dots [2]$$

The foregoing is true only if the hydraulic support cylinders are *frictionless*. If these hydraulic cylinders were of the ordinary hemp-packed plunger type the results obtained would be almost useless as the friction of the packing on the plunger would be very large and the exact amount of this friction would be very difficult if not impossible to determine.

It will therefore be necessary to produce a frictionless hydraulic support cylinder. This, the author believes, has been practically obtained in the cylinder shown in Fig. 3. While it is recognized that no machine can be absolutely frictionless, this cylinder so nearly approaches this ideal state that for all practical purposes it may be considered as frictionless.

The cylinder consists of an upper guide cylinder  $A$  securely bolted to its base  $B$  by sixteen  $\frac{3}{4}$ -in. bolts  $G$ . The base, which is really the cylinder proper, has a groove  $\frac{9}{16}$  in. inside diameter cut into it. The center portion of the base is then faced off to allow just a film of fluid not over  $\frac{1}{16}$  in. in thickness to act on a special stretched-steel diaphragm  $C$  which is securely held in place by the friction between the parts  $A$  and  $B$  of the cylinder and is made tight on its lower side by a soft lead gasket. By this means the fluid is completely confined in the cylinder, the only escape being through the orifice leading to the recording pressure gage. The plunger  $D$  does not come in contact with the fluid in the cylinder but rests on the upper side of the steel diaphragm  $C$ . These contacting surfaces must be very flat and true.

In order to avoid friction between the plunger  $D$  and the side walls of the guide cylinder  $A$  the plunger is turned  $\frac{1}{8}$  in. smaller in diameter than the guide cylinder on its upper parts, and 0.005 in. smaller in diameter where it rests on the diaphragm.

In order to prevent lost motion, or the plunger from tilting and shearing the diaphragm, and further to prevent the plunger from getting "off center" and having a rubbing contact with the cylinder walls, two rings of fifty-six  $\frac{1}{2}$ -in. diameter steel balls each, marked  $F$ , are provided.

The inside diameter of the guide cylinder  $A$  is ground to as nearly a perfect circle as possible and the grooves for the balls are ground and polished to an accurate fit.

When the plunger moves downward due to the application of a load these steel balls tend to lift off their seats and establish a rolling contact between the plunger and cylinder walls.

The only friction on this cylinder is the friction of these ball bearings, the internal friction of the steel in the diaphragm and the friction of the fluid in the pipes leading to their recording gages. These quantities are so small when compared with the maximum load of 250,000 lb. which each cylinder is designed to carry, that they may be neglected.

The displacement of fluid by the plunger when under load is equally small. Marks' Mechanical Engineers' Handbook, page 251, gives the following information: "A pressure of 1 lb. per sq. in. compresses liquids in volume as follows: Water 1 part in 300,000; mercury 1 part in about 4,700,000. For water in an iron pipe this corresponds to a compression of 2 in. per mile of length for a pressure of 10 lb. per sq. in."

It will easily be seen that such a compression of the fluid will not disturb the roll setting. The only other factors entering into the plunger displacement are the quantity of fluid necessary to move the needles of the recording gages and the expansion of

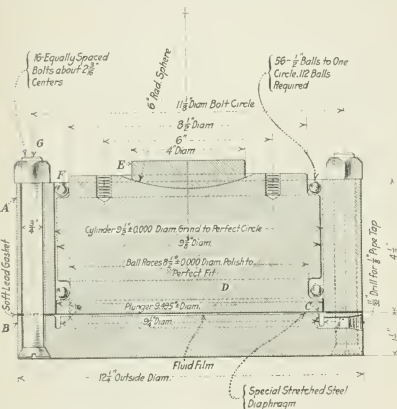

FIG. 3 DETAILS OF FRICTIONLESS HYDRAULIC SUPPORT CYLINDER

back as rapidly as it tends to climb, the angle of sliding friction has been reached and a condition of equilibrium is again established.

These conditions are shown and analyzed in Fig. 2. The pressures on the supporting cylinders will no longer be equally distributed, as in the case of static conditions, but will be much heavier on cylinder No. 1 than on cylinder No. 2.

In the analysis of these conditions the following symbols will be used:

$P$  = Total resultant force on the roll necks in pounds.

$R$  = Radius of the roll neck in inches.

$U$  = The angle whose tangent is the coefficient of friction.

$D$  = Distance from center line of roll housing to center line of supporting cylinder.

$d$  = Distance from center line of roll-neck bearing to the point of contact between the neck and bearing.

$N$  = Some fraction of  $P$  greater than  $\frac{1}{2}$ .

$M$  = Some fraction of  $P$  less than  $\frac{1}{2}$ .

If equilibrium in a "free body" is maintained the following conditions must be met:

1 The sum of all horizontal or vertical forces acting on the body must be equal to zero.

2 The sum of the moments of all forces acting on the body taken about any point must equal zero.

Fulfilling the first condition, as applied to the vertical forces

the short pipes leading to these gages. Both of these factors are so small that they may be neglected.

The idea of this frictionless diaphragm cylinder is not new, but has had several stages in its development. It appears to have been originally invented by Mr. Emery, who first applied it to the well-known testing machine bearing his name. The general application of this invention was delayed by the fact that Mr. Emery measured the pressure in his hydraulic supports by means of a complicated balancing and weighing mechanism. The hydraulic support was made accessible to general use by the research work of Dr. A. Martens at the German Government materials-testing station, who measured the pressure in the hydraulic

and could easily be replaced by a filler casting in case experiments not requiring their use were to be made.

The first cylinder of this type is now in the course of construction and will be carefully tested and calibrated under a 600,000-lb. compression testing machine before the final design is produced for the experimental mill.

Diaphragms varying in thickness from 1-64 in. to 3-64 in. are on hand and their relative merits together with the relative merits of mercury or water for the fluid will be carefully investigated before the final selections are made.

Fig. 4 shows these cylinders applied to the 18-in. three-high bar mill, which are somewhat different from those shown in Figs. 1 and 2. These last-mentioned figures were taken from the 24-in. sheet mill with the neck brass "faked in" for the purpose of better illustration of the mechanical principles involved.

There is one more important item which should be considered before bringing this article to a close. That is the friction of the end of the roll-neck brass on the roll body.

The "thrust plate" marked "1" in Fig. 4 is held firmly against the inside of the roll housing by bolts 2 and 3 and, unless a flexible connection between the lower roll carrier and this thrust plate were provided, would offer a very substantial resisting force acting against the rotating tendency of the lower roll carrier. To overcome this bolts 3 are made with ball joints at their inner and outer ends. In this manner any retarding action due to the stationary thrust plate is avoided. Fig. 5 is a section through this bolt and clearly shows the construction.

The importance of careful experiments on roll-neck friction

FIG. 4 DETAILS OF MILL SHOWING BOLT WITH "BALL JOINT" TO PROVIDE FLEXIBLE CONNECTION BETWEEN THRUST PLATE AND LOWER ROLL CARRIER.

FIG. 5 DETAILS OF BOLT SHOWN IN FIG. 4

will be realized when it is stated that, according to the best information at present available, between 40 and 50 per cent of the total work of a blooming or bar-mill engine is absorbed in friction on the roll necks. These figures represent the best working conditions in rolling-mill practice. For mills such as plate, skelp or sheet mills rolling wide, thin sections, which are often cold, the work lost in friction on the roll necks is frequently between 70 per cent and 80 per cent of the total work of

the engine or motor.

The designs of the experimental mills are being worked out with extreme care, which of necessity involves a slow rate of progress. They offer a great many problems similar to the one just described. It is expected that these designs will be completed some time during the next three or four months and will be given to the public very shortly thereafter.

The Carnegie Institute of Technology is throwing open to members of the Bureau nearly \$400,000 worth of building and equipment, free of all charges for rentals, etc. More than half the money necessary to add this experimental rolling mill has already been definitely subscribed and the remainder is in sight. The completion of this experimental mill will make the Bureau of Rolling Mill Research what is probably the largest and most complete steel research laboratory in the world.

support by means of Bourdon pressure gages and who proved conclusively that the combination of hydraulic support and pressure gages forms the most accurate and desirable means for measuring without friction or lost motion, forces of any magnitude and of any suddenness of application.

Prof. W. Trinks, head of the department of mechanical engineering at the Carnegie Institute of Technology, first conceived the idea of applying cylinders of this type to roll necks sometime early in 1916, and made drawings of a special roll housing for this purpose.

When the author was placed in charge of the organization of the Bureau of Rolling Mill Research and of the designs of the experimental mill he carried the development one step further by designing the present cylinders in such a manner that they would fit in the window of an ordinary roll or pinion housing,

# Steam Use in Textile Processes

By GEORGE H. PERKINS,<sup>1</sup> BOSTON, MASS.

The following paper, presented at the Textile Session of the Annual Meeting of the A.S.M.E., and here given nearly in full, presents tables of comparative figures showing the importance of the use of steam for the manufacturing processes in the textile industry.

Analyses are given of the various uses to which steam is put and suggestions are made for research and improvement of economy.

THE collective textile industries of the United States consume 9,662,600 tons of coal annually and require for their operation a total primary power of 2,495,000 hp. of which 66.8 per cent. or 1,665,900 hp., is developed by steam prime movers.

Tables 1 and 2 give figures compiled from the United States Census of Manufactures for 1914, showing the distribution of coal and primary power to the seven principal manufacturing groups included in the textile industry. These figures serve to emphasize the magnitude of the steam requirements of this industry, which are to be considered in this paper with particular reference to the heat demands of textile processes.

## RELATIVE ECONOMY OF TEXTILE INDUSTRIES

The relative fuel economy of the different textile groups is shown in Table 3, derived from data given in Tables 1 and 2. The items are listed in the order of comparative performance as figured on a common basis of power production and show clearly the effect on the overall economy of the extensive use of steam in the various processes of manufacture.

The cotton goods and cordage groups rank first, owing to their small demands for process steam. The relatively good economy shown by the woolen and worsted group may be attributed to a more general utilization of exhaust steam in processes and the better balance usually existing between the steam demands of prime movers and processes.

The dyeing and finishing group has a comparatively small power demand and a most extensive use for process steam. The relation of coal to power in the silk goods group appears out of proportion in comparison with the other industries and must be attributed, in part, to the wasteful use of steam and a more extensive use of the lower grades of fuel.

The validity of the results given in Table 3 may best be shown by citing a number of specific examples of individual plants of different types, giving the actual fuel consumption and power production. This is shown in Table 4. These figures check well with the averages for the respective groups which are given in Table 3.

## IMPORTANCE OF HEAT APPLICATIONS

The foregoing facts emphasize in general terms the importance of the problems of heat application to textile processes. These problems warrant far greater attention than they have yet received, both from the standpoint of production efficiency and from the consideration of fuel economy. But little progress has been made along either line in comparison with the marked advances that have taken place in the art of generating steam and power.

Many textile power plants are "saving at the spigot and wasting at the plug," and the average dyehouse, bleachery or print works is usually considered a necessary evil to be endured up to the limit of the boiler capacity of the plant. While production efficiency must be considered as of the first importance, the present fuel situation demands rigid conservation in the use of both coal and steam.

## EFFECTS OF HEAT ON TEXTILE MATERIAL

The purposes for which heat is applied to textile materials in process are numerous and varied and only the principal ones will be summarized, as follows:

Process	Material	Purpose or Effect of Heat
Scouring	Wool	To assist the action of the soap and alkali.
Carbonizing	Wools and shoddies	To free the acid from moisture to permit carbonization.
Combing	Worsted wools	To facilitate drawing through the pins.
Dyeing	All materials	To assist the fixation of dye-stuffs.
Kier Boiling	Cotton goods	To assist action of liquor in softening impurities.
Drying	All materials	Evaporation and removal of moisture.
Tentering	Cotton and worsted goods	To dry goods under tension retaining width.
Steaming	Woolen, worsted and print goods	To shrink, remove glaze and to set fabrics and colors.
Soaping	Print and dyed goods	Warm water removes surplus color and improves appearance
Ageing	Print and dyed goods	To set or develop colors.
Washing	Woolen and worsted goods	Warm water removes oil and soap applied in previous processes.
Pressing	Woolen and worsted goods	With pressure, flattens surface for finish effect.
Calendering	Cotton goods	With pressure and friction, assists in producing luster.

## CLASSIFICATION OF PRINCIPAL HEAT-USING PROCESSES

Application	Machines of Similar Use
Direct contact of materials with steam or water vapor	Steamers for woolen goods, print goods, etc. Ageing machines for print and dyed goods Yarn conditioning machines
Direct contact of materials with heated surfaces for warming stock, pressing, polishing, drying, etc.	Worsted comb steam chests Worsted back washers Plate presses for woolen goods Rotary presses for woolen goods Slashers and dressers Cylinders and can dryers Calenders for cotton goods Polishers for twine, thread, etc.
Drying of materials with air heated by direct or indirect radiation	Hot air slashers and dressers Cotton and wool stock dryers Carbonizing dryers Cloth dryers Shrinking dryers Tenter frames Dry rooms for yarn Back washer dryers
Direct use of steam for boiling or heating liquids and use of warm water	Dye tubs and dyeing machines Scouring bowls for wool Bleaching kiers Cloth washers Crabbing machines Starch and size cooking Soapers
Indirect use of steam for heating liquids.	Bleaching kiers with closed heaters and circulating pumps. Jacketed kettles for size, starch or dye-stuffs. Tubs and dyeing machines with closed submerged coils. Preheating of liquids for process or storage by closed heaters.

The direct or indirect heating of rooms containing processes requiring careful temperature and humidity control may also be mentioned under the general heading.

## FACTORS AFFECTING PRODUCTION AND ECONOMY

Some of the various conditions commonly found, which affect either production or economy are as follows:

<sup>1</sup> Consulting Engineer, 34 Batterymarch St. Mem. Am. Soc. M. E.

Production	Economy
Wet steam.	Leakage from traps, vents, etc.
Poorly designed steam distribution system.	Wasted drips.
Incorrect arrangement of traps.	Overheating or overcooling through careless operation.
Deficient trap capacity.	Radiation losses through dryer housings, etc.
Delays in heating liquor, dyes, etc.	Waste of exhaust steam or condensing water.
Inefficient air circulation in dryers.	Lack of hot-water storage.
Deficient dryer radiation.	Failure to recirculate air in dryers.

In addition to the data given above, there is usually little information available either of the steam requirements or

FIG. 1 TEMPERATURE RISE AND STEAM CONSUMPTION IN KIER TEST

demands. While considerable progress is being made in means and methods for correcting the conditions mentioned, there is still room for much improvement.

Many of the larger mills are making complete steam surveys of their plants periodically to check use against demand and also to enable steam costs to be properly apportioned to the various processes. Modern steam meters give reliable results and in-

FIG. 2 TEMPERATURE RISE AND STEAM CONSUMPTION IN DYE-TUB TEST

variably reveal many surprising conditions which require attention and which cannot be disclosed by any other means.

#### TEST RESULTS

The results of tests made at different plants are given in the following tabular form, and in Figs. 1 and 2, merely to illustrate common practice and not as standards of high performance. They will however be found useful for comparative purposes.

#### SUGGESTIONS FOR INVESTIGATION AND IMPROVEMENT

It is hoped that the outline given of this subject will help to stimulate greater attention to this important matter.

The following suggestions are offered as concrete lines for useful and practical study and research:

- Further investigation of conditions of temperature, humidity and air circulation for drying various materials with maximum production and minimum heat consumption
- Development of more efficient arrangement of radiation and air circulation in dryers
- Automatic control of the production rate of dryers, through conditions resulting from drying results obtained
- Further development and application of temperature control devices to heat using processes
- More effective utilization of exhaust steam in processes, heating water storage, etc.
- Recovery of heat from spent and rejected liquors.
- Development of insulating materials to be used under conditions where equipment is subject to extreme moisture conditions or to mechanical injury
- Use of supplementary air circulation with can dryers.

The field is a broad one with many varied and complex problems, but the coöperative effort of manufacturers, machine builders and engineers should bring about much needed improvement in the present average practice.

# The Causes of Industrial Unrest and the Remedy

Labor Unions Have Promoted Inefficiency and Decreased Production—Employers Have Been Remiss in Regard to Industrial Relations—Each Shop Must Work Out Its Own Salvation Through Fair, Cordial and Sympathetic Co-operation

By FREDERICK P. FISH, BOSTON, MASS.

**E**VEN under normal conditions, there is no phase of our modern social organization which is more complicated and exacts more from the intelligence, character and capacity of mankind than the machinery and methods of production and distribution by means of which our material needs are satisfied. But at the present time, conditions are not normal. Everything has been thrown out of adjustment by the Great War. There has been a destruction of property, the effect of which will embarrass us for years, and millions of men who would have worked and produced have been killed or incapacitated. But this is not all. The thought of the whole world has been disturbed. A condition almost approaching hysteria has been developed so that everywhere men are incapable of cool, sane judgment not only as to the facts of the existing situation but as to their needs and aspirations.

## DECREASED PRODUCTION AND ITS CAUSES

Leaving out of consideration all matters of governmental disturbance and confining our thought only to production, it seems certain that at the very time when there should be the greatest effort to produce, that we may make up for the losses of the last five years and establish our material resources on a sound basis, the attitude of workmen throughout the world is such that individually and as a whole their efficiency and productive power are much less than before the war. While in other parts of the world they are working under unfavorable conditions, that is not the case in this country. Here the sole reason for reduced efficiency is the atmosphere that has been developed, which results not only in strikes but in a definite attitude on the part of the worker that he will not produce to the extent of his reasonable ability. In spite of the fact that he is constantly demanding greater pay, he is insisting upon shorter hours and is disinclined to exert himself while at work. He almost cultivates a spirit of antagonism to the enterprise for which he works, forgetting that his interests and those of his employer are identical and that only by close coöperation can results be attained that will lead to the prosperity of either. The influence of labor unions, not only in the "closed shop," where with the acquiescence of the employer they largely dominate the situation, but in many of the so-called "open shops," in which are labor-union workmen influenced by the principles of the labor unions, is such as to promote inefficiency on the part of the workmen. Some deliberately refrain from effort, but I believe it to be the case with a large majority that, against their inclination, they fail to make proper effort because of fear. They do not dare to act contrary to the spirit instilled by the labor unions and labor-union men, which causes them to be treated as traitors to their class if they do all that they would gladly do by way of loyal devotion to their work.

Only this week the manager of a large plant told me casually of some of the conditions with which he has to contend. In one room where a large number of workmen are assembling a certain article, each and every one of them produces exactly fifty a day and twenty-five a half-day of the working period. It is, of course, absurd to suppose that the capacity of each and all of a

very large number of workmen should be so uniform as to lead to this result, unless there was a standard deliberately adopted and maintained. This same manager told of another circumstance which illustrates the same spirit. He has procured a machine which with one man will do the work heretofore done by eight men. Up to date he has been utterly unable to find a man in his establishment who will run that machine. The absurd fallacy that it is for the interest of wage earners that each should do little work, ineffectively, that more may be employed, prevails to a substantial extent under the influence of the labor unions.

In this plant to which I have just referred, wages have increased on the average 110 per cent since 1914, although the cost of living has not increased more than about 75 per cent, and the manager is satisfied that the efficiency of the individual workmen has been reduced during the same period about 40 per cent.

There is ample testimony that the situation is the same throughout the country.

Of course, it is the public, the consumer, that ultimately suffers from such failure on the part of the workers to recognize their duty as factors in production. For the moment at least, owing to the abnormal situation throughout the world, the employers are able to add to the price of their manufactured articles enough to make up for this absurdly unnecessary and vicious added cost of production, so that the public pays the bill. But such conditions cannot continue, and the time is surely coming when our industries will be unable to recoup themselves in this manner, with a resulting period of industrial depression which may well be the most serious in history.

## REASONS FOR THE PRESENT UNSATISFACTORY EMPLOYMENT RELATIONS

What is the reason for these unsatisfactory employment relations and how can they be cured? To answer these questions, brief reference must be made to certain facts of recent industrial history, the importance of which should be clearly understood.

While the present unsatisfactory conditions have been accentuated by the war, they had existed, although to a lesser degree, for many years prior to 1914 in this country and even to a greater extent in England.

I believe the fundamental difficulty to be that industry has not had time to adjust itself to the extraordinary new conditions that have prevailed during the past forty or fifty years. While there is no more wonderful chapter in the history of the world than that of industrial progress during the period above mentioned, those who were in control of the industries and directed their progress and upon whom was the duty of assuring satisfactory employment relations under all conditions of effort, were so absorbed in the tremendous task of meeting the material advances in the arts, in responding to the vital changes in industrial methods and in securing the proper utilization of new and extraordinary resources that were for the first time available, that they overlooked and neglected the essential matter of properly adjusting the employment relation to new conditions.

The result of all this progress was great corporations and great manufacturing establishments such as were not even fore-shadowed in former days, attended by the extraordinary development of power and of machinery on a large scale which was based upon marvelous inventions and striking achievements in engineering such as the world had never seen. Craft and hand-

<sup>1</sup> Chairman National Industrial Conference Board.

This contribution and the two succeeding ones, by Dr. Leiserson and Dean Heilman, were given at the Industrial Relations sessions of the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, December, 1919. These three addresses, and the paper by Mr. A. L. De Leuw on Wage Payment, published in the December, 1919, number, constitute a symposium on "The Industrial Situation in Relation to Present Conditions," a general account of which is given elsewhere in the present issue. These addresses are here given in abstract and are subject to revision.

work were to a large extent eliminated. Vast numbers of workmen were brought together in individual factories, where their activities were specialized to such an extent that each man became trained to a high degree of efficiency in some line to which he devoted his energies exclusively. Only by organization of the most complicated character was it possible to deal with these new conditions; and organization took the place of that personal and direct control by management which had formerly prevailed. In such a radically new environment it was impossible for employment relations to remain as they were before. They inevitably required readjustment. Personal touch between the employer and employee, such as had existed from the beginning of history, was no longer possible. Where such personal relations exist there must be serious fault on one side or the other if they are not harmonious.

If organization is to take the place of such personal contact, it must be made to fit the conditions.

There can be no doubt that the achievements of those who have been responsible for our industrial development during the last fifty years are worthy of the greatest praise. They were secured by a wonderful exhibition of power, intelligence and capacity on the part of a large number of devoted servants of industry. But in the stress and strain of their efforts they could not cover the whole ground. Some aspects of the situation were neglected.

One illustration of this is familiar to us all. As business interests and business men became more and more efficient and powerful, evils appeared such as always attend a great and sudden social movement accompanied by strenuous effort and marked success. Those evils were due to the same weakness of human nature which has caused the bad to be mingled with the good in every great forward step in the progress of our race, whether in religion, in methods of government or in measures of social reform. They arose because management failed adequately to correlate industrial progress with the public interest.

The time came when the public dealt in its own crude way with a situation which it did not approve. Some twenty-five or thirty years ago it became persuaded that the "captains of industry," whom the public had idealized up to that time, and their associates, were developing the industries on lines that seemed contrary to the general interest. Big business became unpopular. The result was a public sentiment which, while it has undoubtedly brought about a needed reform in industrial methods and the relations of industries to the community, has surely been carried so far as to embarrass business to the disadvantage of society. Such a reaction was inevitable, for the people will and should resent the exercise of undue power on the part of

any class, no matter what may be its obligation to that class for real service.

Another direction in which management failed to do its full duty was in the employment relation. It proceeded in its strenuous efforts to advance the industries without recognizing that the conditions of employment were such that they required to be approached from a new point of view. Things were allowed to drift and finally came to a point, even before the war, which threatened trouble of a deep-seated and far-reaching character.

We now see clearly that enough attention was not given to the conditions under which men worked, to the principles upon which their compensation should be determined, to their health and comfort not only in the factory but at home. We recognize that the new and strenuous activities forced upon the workmen by modern machinery, which often determine the pace at which men shall work, required careful study that the length of the working day might be properly determined in view of the new environment in which the work was carried on. Enough attention was not paid to the effect upon the workmen of the intense specialization and concentration of their work, as compared with the greater variety and slower methods of former days. Due consideration was not given to the question whether or not the fundamental law of supply and demand, which will always be potent in determining the workman's compensation, might not properly be supplemented to some extent by other considerations. The serious matters of unemployment and the current practice, which seemed unavoidable, of hiring many men to secure a few, were not strongly dealt with.

If these subjects had been studied and the new problems properly worked out, there is no doubt in my mind that the feeling of dissatisfaction, almost of antagonism, on the part of the workmen that finally came into the industries would, to a large extent, have been avoided. It must not be forgotten that contented workmen, whose surroundings are satisfactory and whose health and comfort are maintained, are likely to work so efficiently as more than to compensate for the shortening of hours of work, if they are too long, and for the expense involved in giving them surroundings conducive to health and reasonable comfort; and that added efficiency

is promoted by and should be recognized to some extent by increased remuneration, irrespective of what may be called the "market rate" for labor.

As discontent grew among the wage earners, and employers did not wake up to the necessity of trying to meet their aspirations, reasonable or unreasonable, as to better working conditions, and of educating them to sound views of the matter, it

*"The influence of labor unions, not only in the 'closed shop,' where with the acquiescence of the employer they largely dominate the situation, but in many of the so-called 'open shops,' in which are labor-union workmen influenced by the principles of the labor unions, is such as to promote inefficiency on the part of the workmen."*

*"They seem determined to carry on their war against civilized society, for that is what it really is, to the limit and to secure if possible the control of our industries by threats and force. If they should succeed by such methods, a law of brute force would be established which would mean the end of our Government and of society."*

*"There is no doubt, however, that the labor unions have also accomplished much good. Among other things they have focused the attention of industrial management and of the public upon those features of employment relations which needed study and revision. It may even be possible that the vicious methods of the strike and the boycott and the brutal and even criminal pressure brought by the trade unions upon non-union workmen and their families, as well as upon employers, have contributed to opening the whole question for proper consideration."*

*"There can be no specific general cure, no panacea for the evils that exist, either by way of legislation or of reorganization of our social or industrial methods; but the present unfortunate antagonism between employers and employees and the existing disturbance of the cordial feeling that should exist between them can be eliminated and right conditions restored only by definite personal effort to develop and maintain, in the individual industrial establishments of the country, suitable employment relations, based in each instance upon fair, cordial and sympathetic coöperation and a recognition of what is right and proper in the particular establishment."*

FREDERICK P. FISH.

was but natural that the trade and labor unions should succeed in bringing many workmen into labor organizations which seemed to them to promise relief from what they regarded as unsatisfactory working conditions. There is no doubt that the labor unions have accomplished much good. Among other things—and this is probably where they have been of chief value—they have focused the attention of industrial management and of the public upon those features of employment relations which needed study and revision. It may even be possible that the vicious methods of the strike and the boycott and the brutal and even criminal pressure brought by the trade unions upon non-union workmen and their families, as well as upon employers, have contributed to opening the whole question for proper consideration.

#### ARBITRARY ATTITUDE OF LABOR UNIONS

But from the beginning the labor unions have adopted social and economic principles that were unsound and methods of propaganda and of action that should not be tolerated in any civilized society. They have worked for the suppression of production upon the false theory that the less men worked, the more men could be employed. On the same ground they have not been sympathetic to the introduction of improved machinery and have often opposed its use. They have undertaken to establish a closed organization which would prevent the employment of workmen who would not yield themselves body and soul to the dictation of labor-union leaders. In this way they have been the enemies of society and of unorganized labor. They have been opposed to apprenticeship systems and vocational education as likely to add to the number of competitors for the jobs of labor-union men. They have undertaken to enforce arbitrary and unreasonable rules in factories and to interfere with the proper execution by the management of its necessary prerogative of control. Not to speak of such crimes as those of the McNamaras, they have often violated the laws of the land as well as the principles of good morals. They have fostered and encouraged mob rule. They have tacitly and even directly encouraged assault and destruction of property as a means of winning the strikes upon which they relied for accomplishing their purposes. They have refused to be bound by the law and have too frequently, by the exercise of pernicious political influence based largely upon threats, obtained special exemptions from provisions of law than no one else could violate with impunity. They have practiced intimidation on the wives and families of workers and interfered with the inherent right which every man has, to choose his own way of getting a living, provided it is lawful.

They have used the fact that they were rich and powerful organizations, purporting to speak for a large number of men—who were, in theory, bound to work and vote as a unit—to further legislation for their own selfish purposes and not in the public interest. They have openly expressed disrespect for the law and courts and have shown that disrespect by their conduct. All these charges are capable of proof and are recognized as valid by those who are familiar with such matters.

There is no doubt that many of the labor-union leaders have been good men, working for what they regarded as the interests of the workmen. It is also a fact that some individual labor unions have been so reasonable in their activities that employers have found it possible to work with them with satisfactory results. But generally speaking, such has not been the situation. It is always the case in such organizations that a small element of active, virile and intelligent leaders, carried away by the desire for power and by their own ambitions, find themselves almost instinctively adopting such wrong and brutal methods as the exigencies of the case seem to require, on the theory that the end justifies the means. Moreover, their hands are forced by what they regard as the necessity of getting results. The majority of those who follow them are naturally good and law-abiding citizens, but in addition to the fact that pressure, even to the point of violence, is brought to bear upon them and their families, they become blinded in their devotion to the cause and fail to

see things in true perspective; even if they do not approve of what is done in their name and ostensibly on their behalf, they have no power to control the situation. They are carried along by a stream too strong to permit the exercise of individual judgment.

Up to the time of the war, the American Federation of Labor, which stood for the recognized labor unions in this country, had succeeded in securing a membership of less than 10 per cent of the workers in industry. Considerably less than 10 per cent of the shops in the country were "closed shops," that is to say, shops in which the labor unions dominated. The "open shop" principle had been substantially maintained. This country therefore did not suffer as it would inevitably have suffered if the labor unions had been really a dominant force. In England, where they had been much more successful in securing the control of the employment relation, the consequences of their power and influence were clearly seen. Before the war, the individual American workman was turning out from two to three times the product turned out by the English workman. Because of his greater productive power, his wages were higher and his living conditions much better than in England. In the latter country, production was so reduced by labor-union rules and by the hostility to improved machinery, fostered by the labor unions, that England was rapidly losing her standing as a manufacturing nation, while at the same time wages and the standards of living of her workmen were extremely low. This was inevitable, for there was no large production from which good wages could be paid, large production being the only source from which increased returns to the workers can be derived.

When the war broke out, England found that under existing conditions she could not begin to produce what was required for fighting purposes and the support of her army and her people. There was only one thing to do, which was to persuade the labor unions to suspend their rules and abandon their characteristic methods during the period of the war. By great pressure from the Government they were induced to take this course, with the result that production was increased in England to an astonishing degree; but the labor unions made this sacrifice of what they regarded as their interests, only with the distinct understanding that, after the war, they should be allowed to reinstate themselves as a controlling force in industry. They are now trying to bring about this revival of the old condition of things. If they succeed, England as an industrial nation is doomed.

When we entered the war there seemed to be a fear, which was probably unfounded, that the organized workmen in this country had no patriotism and no thought of the public welfare. There seemed also to be a feeling on the part of those in power that the labor unions, represented by the American Federation of Labor, controlled the situation and must be placated in any event. There probably was no foundation for this feeling, but on this theory the entire influence of the Government during the war was on the side of yielding everything to the labor unions. The Government throughout the war seems largely to have followed the dictation of the labor unions. It certainly used its influence to force the employers of the country to yield to the organized workmen practically everything that was demanded, not only as to wages and working conditions but in the matter of unionizing the shops. This seems to have been the uniform policy from the date of the Adamson Bill, which was the first expression of it on a large scale.

The results have been that while every other section of the community, including unorganized labor, made substantial financial sacrifices to aid in winning the war, workmen in industry have been called upon to make no such sacrifice. Their wages have gone up far more than has the cost of living and today they are the conspicuous class in the community which has money to spend on luxuries to an extent never known before. And yet, during the war organized labor promoted an infinite number of strikes to the great embarrassment of the Government and loss to the public. Many and perhaps most of these strikes centered about the question of recognition of the labor unions by the employers.

## DETERMINATION OF LABOR UNIONS TO DOMINATE INDUSTRY

The great increase in power and influence which the labor unions have secured as the immediate result of the war, as well as their determination to dominate industry at all costs, is reflected in the steel strike, the coal strike and innumerable other strikes throughout the country, while one phase of their aspirations is illustrated by the strike of the Boston police. They threaten a railroad strike and even a general strike unless their demands, which are clearly unreasonable, are complied with. Either would cause intolerable hardship to the community. They seem determined to carry on their war against civilized society, for that is what it really is, to the limit and to secure if possible the control of our industries by threats and force. If they should succeed by such methods, a law of brute force would be established which would mean the end of our Government and of our society. There is no need to argue what a serious matter this would be for our industrial prosperity. But it also should be noted that if the labor unions succeed in this effort, they will establish an *imperium in imperio* in this country which will be utterly inconsistent with proper Governmental control and with the ideals of a free, democratic community.

There are at the outside something more than four million workmen who are members of the labor unions, not over 10 per cent of all the wage earners in the country. More than that, there is reason to believe that a substantial number of the men in the labor unions do not sympathize with the underlying aspirations of the leaders or the methods adopted by them. The recent election in Massachusetts is an indication that the workmen of this country are not in sympathy with such high-handed procedure. And there is much further evidence to the same effect.

In addition to the trade and labor unions associated with and in the American Federation of Labor, there are other labor unions of the same type, of which the railroad brotherhoods are the strongest and most important. There are also other associations of wage earners to which a brief reference must be made. Many of these, the so-called Independent Workers of the World being the most conspicuous, are distinctly revolutionary in character and criminal in act and intent. The normal American workman has no sympathy with their real aims and purposes, but some are deceived into believing that they will help to secure better conditions of living. The greatest strength of these lawless organizations is with the foreign-born worker who is not at all an American and whom it is easy to mislead. They are, in theory, opposed by the trade and labor unions partly because it is the policy of those last-named organizations to resent the intimation that they are aiming at the destruction of society and partly because their leaders are afraid that, by some wave of sentiment, the rank and file of the labor unions may be carried over into the other and more radical camp and new labor-union leaders selected in the place of those now in power.

It cannot be overlooked, however, that while the trade and labor unions have stood in opposition to the I. W. W. organization, and others like it, and have proclaimed their hostility to the destructive and revolutionary policy of such organizations, they themselves in their underlying principles, as well as in their practices and conduct, have laid the foundation for just such revolutionary and destructive ideas as those which their rivals have openly proclaimed and promoted.

It is incredible that at the present time there should be any danger of such public support of these revolutionary organizations as would make them a serious menace to our industries, to our Government and to our civilization. There is far greater danger that the trade and labor unions may play a conspicuous part in the future of our country, for at any rate until recently the people as a whole, carried away by sympathy, have been inclined to overlook their faults and even their crimes and to regard their activities with a certain degree of favor. The real question is this: Shall a series of organizations, welded into one great parent organization of enormous wealth and strength, be allowed to have and to exercise such power that it may at will paralyze our industries, and by methods such as are illustrated by the great strikes above referred to, and by threats—even threats to starve our people—attempt to secure its own selfish

ends irrespective of the interests of the rest of the community? The answer to this question seems clear.

The same instinct on the part of the public which led to the more or less warranted attack upon big business some twenty years ago should bring about among our people a recognition of the tremendous danger involved in the improper and brutal exercise of power threatened by the labor unions. If public sentiment is once aroused, the end is certain. The American people will surely not submit to the domination of any class working solely in its own supposed interest for power such as no class should have.

The extraordinary efforts now made by labor unions have as their foundation no present grievance on the part of the workingman, for none of any real moment exists. The unions are simply taking advantage of the condition of dissatisfaction and mental disturbance on the part of the wage earners, the beginnings of which were before the war but which have been fostered and promoted by the circumstances of the war period. So long as that mental and moral condition continues, the field is open for labor-union propaganda and worse. If they succeed in their efforts the result will surely be inefficiency of production, inharmonious employment relations and the possibility of even worse developments along the lines of the aspirations of those who would destroy our civilization and our Government.

## HOW TO REMEDY THE EXISTING SITUATION

I have tried briefly to present certain phases of the existing situation and to show in part how present conditions arose. The great question, and it is the most serious with which we are now confronted, is how to deal with this existing situation. There are some, even among those who are intelligent and have given more or less attention to the subject, who seem inclined to believe that the solution of the present difficulties in the employment relation resides in the further development of the trade and labor unions and of their policies. They picture a condition of things in which all workers are organized and perhaps all employers in like manner organized. Then the labor unions on the one hand and the employer organizations on the other are to get together and by "collective bargaining" settle for all the industries all questions of wages, hours of labor, conditions of employment and other relations between employer and employee.

I am convinced that such a plan, if adopted, would be destructive of our industries and fatal to our prosperity and to our life as a free people. The whole history of the labor unions in this country and abroad shows that the result would be marked inefficiency, limited production and no real improvement in the relations of the wage earners and the employers. It is to me inconceivable that any one who has studied the subject should come to the conclusion that such a plan is even to be seriously considered.

Others talk loosely of the "democratization of industry," a vague phrase which seems to imply a more definite participation on the part of the workmen not only in the control of employment relations but even in management.

There is no reason to believe that the workmen themselves have any such aspirations and it is certain that the right and obligation of management to exercise its necessary function of direction and control must always be definitely recognized and maintained. Such suggestions are too vague for intelligent consideration.

## NO PANACEA AVAILABLE FOR EXISTING EVILS

It is my firm conviction that there can be no specific general cure, no panacea for the evils that exist, either by way of legislation or of reorganization of our social or industrial methods; but that the present unfortunate antagonism between employers and employees and the existing disturbance of the cordial feeling that should exist between them can be eliminated and right conditions restored only by definite personal effort to develop and maintain, in the individual industrial establishments of the country, suitable employment relations, based in each instance upon

fair, cordial and sympathetic coöperation and a recognition of what is right and proper in the particular establishment.

Not only is the cost of labor far and away the largest item in practically all industry but men and women, unlike machinery, to a large extent control their own actions even when under discipline and must not only be trained but must be in the right frame of mind. If they work in a cordial spirit and with good will, the results are far greater than if their efforts are perfunctory. It would seem certain that an intensive study of this human relation in an industrial establishment would result to even greater advantage than the same amount of attention given to the material factors.

In this direction much has been done during the past few years and with good results. There has been a marked improvement in working conditions throughout the country. Sanitary and hygienic arrangements and devices protecting against danger have been introduced to a large extent. Shop hospitals and nurses are common in the industries. Definite and well-considered efforts have been made to promote the living and housing conditions of employees and to give them opportunity for healthy and stimulating physical and mental recreation.

#### IMPROVED WORKING CONDITIONS BETTER EMPLOYMENT RELATIONS

There is no doubt that the employment relations have been bettered by these improvements in working and living conditions. They must have resulted in better health and greater efficiency and have developed a better feeling on the part of the workers.

Such methods should be adopted in every establishment to the extent to which they are justified by the conditions in that establishment, not only as a plain duty to the workmen but because they are a profitable investment leading to better service. Everything, of course, depends upon the spirit in which such efforts are made and accepted by the workmen. If they come as a natural, reasonable incident to the employment relation and not in such a way as to offend the just pride of the employee, their effect must be wholly good.

But such efforts are not enough. The workman is primarily interested in the more essential matters of wages, hours of labor, continuity of employment, and the fairness of the rules and regulations under which he works and of the spirit in which those rules and regulations are applied.

In all these matters he has inevitably personal views to which consideration should certainly be given, not to an extent which will interfere with the necessary control by management, but to an extent which will enable management to act intelligently and sympathetically. If in such matters the workmen can be made to feel that they are treated as men, with rights that are recognized and respected, they will surely be in a much better frame of mind and more likely to respond with a reasonable view as to that to which they are entitled.

It is not unnatural that while they must take orders and must work under rules that are essential to the carrying on of the business, they should feel dissatisfied if they have nothing to say as to their wages, hours of work and working conditions, but are in a position where they must take without protest what is offered to them or give up their job. No man likes to have another say to him, "Take it or leave it," without explanation or discussion.

It therefore seems certain that in each individual industrial establishment there should be the same scientific effort to study the men in their relations to the work as to analyze the materials, machinery and shop methods, in order that the best possible results may be produced. If instead of holding the workmen at arm's length, they could be taken into the confidence of the employer as to wages, hours and working conditions, it seems but reasonable to believe that a feeling of mutual confidence and willing coöperation would be developed which would be a most distinct asset to the business and likely to hold the men against any of the superficial inducements offered by trade and labor unions, which endeavor to excite antagonism on the part of the workmen toward the enterprise in which they are essential factors.

The burden of the effort to bring about such relations must be

consciously and definitely assumed by the management in each individual establishment. From that management the initiative must come with the hope that the employees will respond.

#### EACH EMPLOYER MUST SOLVE HIS OWN PROBLEM

No hard and fast rules on the subject can be laid down. Each employer should study his own problem and attempt to deal with it in view of the conditions in his own establishment, exactly as he works out his mechanical and technical problems in harmony with the requirements of his own work and with only general reliance on the experience of others.

Of the 450,000 manufacturing establishments in this country, the large majority are so small that it is still possible for the old-fashioned personal contact between employer and employee to continue. In such cases all that may need to be done is that the employer should treat his workmen as reasonable beings, whose inevitable interest in their own affairs entitles their views to frank sympathetic consideration. He should not hold them at arm's length. He should learn their ideas and their criticisms of their relations with him. He should endeavor to satisfy them of the reasonableness of his attitude in the matters that are of such vital importance to them. He should see that they understand the conditions of the business. He should let them know why the wages and hours of labor should be fixed at a certain standard and the reasons for the rules and regulations that are adopted. He should acquaint them with the difficulties under which he labors, in so far as those difficulties are material to a full understanding of the exact situation. He should invite their suggestions as to ways, large and small, by which shop methods may be improved or the product and quality of the goods increased. He should be willing to discuss with them, under proper conditions, all the questions in which employer and employee are jointly interested. He should listen to the complaints of the men, recognizing that if matters of complaint are dealt with promptly it is generally easy to dispose of them.

All this could be done by an intelligent, sympathetic employer without the expenditure of much time or effort, and there is no doubt that he would find a real satisfaction in the energy so expended.

Where the number of men employed is so large that personal contact is impossible, each employer should make every effort to work out a plan by which, in view of the conditions in his own establishment, he can get the equivalent of such personal contact. There is more than one way of bringing about this result. In some cases, it might be accomplished by the organization of a special department whose duty it would be to keep in close touch with the men and establish with them the confidential relations that are required.

#### GOOD RESULTS FROM ESTABLISHING SHOP COUNCILS

Another plan that seems promising and which has already been adopted in several hundred establishments in this country, in some of which it is working with marked success, is the establishment of shop councils or some other form of shop or plant organization by which representatives of the employees, honestly selected by them from their own number, meet regularly with representatives of the employer to consider, in conference, the questions arising under the employment relation.

There is every reason why the employees should welcome such an opportunity to meet representatives of the employer. Such an arrangement would appeal to the sense of fairness of the employees and if the conferences were conducted as they should be on terms of perfect equality and with entire frankness, the results could not be other than beneficial. Experience seems to show, what it is only natural to expect, that representatives of the men selected for such purposes, under conditions which insure an honest election and a fair count, would be intelligent and reasonable. Through them the men would learn much that they never otherwise would know as to the troubles and aspirations of the management, the difficulties of carrying on the business

and the reasons for the adoption of one policy or another in the employment relation.

If the workmen are not satisfied with some phase of the terms of employment or with some feature of the rules imposed upon them, or have a complaint against any particular foreman or other person in the establishment, or if an individual workman has some personal grievance, such conferences would bring the matters complained of to the attention of the management at an early stage, before the workmen have become demoralized by brooding on the subject, and, if dealt with promptly and fairly, there would be less danger that a small grievance would lead to serious trouble. Through their representatives, the workmen could be taught sound economic principles such, for example, as the fact that good wages and national prosperity as well depend upon efficient service and large production. They could be made to see that if it is reasonable that wages should respond to improved conditions of business, it is equally reasonable that if business declines, wages should be reduced. There would be an opportunity that would otherwise not exist to present to the workman the reasons why, from the point of view of his own selfish interest as well as that of the public good, a reduction of the hours of labor below the point of maximum production consistent with the health and reasonable comfort of the worker is a fatal mistake. At and by such conferences the workmen should be encouraged to make suggestions as to the improvement of shop methods, large or small. Many workmen are unquestionably capable of real help in this way. They could be made to realize that they were a vital element in the work whose co-operation in all ways was needed and expected. To such suggestions they would surely be inclined to respond.

It would seem that if in every one of the industrial establishments of the country a definite effort was made on the part of the management to bring about directly or indirectly such personal contact between the employer and employee as would result in a frank discussion of the employment relation and those matters concerned with the enterprise in which the employees are necessarily and vitally interested, and a definite recognition of the workmen as essential factors in the enterprise, antagonism might be eliminated and relations of loyalty and confidence established to an extent that would be most fruitful in good results.

It goes without saying that nothing can be accomplished by mere machinery. The right spirit must be developed on both sides; but it is unreasonable to suppose that it is impossible to develop that right spirit. In any event, it would, in my opinion, be a red-letter day not only for industry but for the public if all the employers of the land were to start in to bring about an improvement in employment relations by the very simple expedient of working, each in his own establishment, to see what could be done by personal contact between employer and employee to inspire confidence, harmony and co-operation.

#### SELECTION OF EMPLOYEES' REPRESENTATIVES

In any such shop organizations as those above referred to, it is of vital importance that the representatives of the employees should be honestly chosen, and chosen from among the employees themselves and not from the labor unions. Otherwise, the labor unions would find it necessary to enlist as members only a small portion of the employees in any given establishment and that minority, acting as a unit, would be able to elect walking delegates or other members of the union as representatives of the whole body of employees. If that happened and the employer was obliged to meet these labor-union agents as the representatives of his men, his fate would be sealed. An "open shop" employer would surely find himself forced to the union shop, first, by the pressure of the negotiations, and, second, by the moral effect upon his own men, exaggerated by the skillful way in which the labor unions would utilize the fact that they and they alone through the prestige of their union were maintaining the rights and promoting the interests of the employees.

It is futile to contend that the employees in any given establishment cannot find among their own number men who are quite

competent to represent them fairly in conference with representatives of the employer. In every shop there are many workmen quite capable of presenting their own views and those of their fellows in a most effective fashion. Such men are sure to be elected by the workmen as their representatives.

#### ADVANTAGES OBTAINED FROM A WELL-ORGANIZED EMPLOYMENT DEPARTMENT

Another direction in which effort should be made by the management in each individual establishment to better the conditions of the employees and improve the employment relation is in the matter of unemployment and of hiring, placing and discharging. Unnecessary unemployment is one of the most serious incidents of modern industry. It undoubtedly has much to do with the discontent of the workmen. The subject has been given much less careful attention than its importance deserves.

Here again much can be accomplished by intelligent management in the individual industrial establishment. Nothing could be more absurd than the hiring of men without a careful examination into their fitness for the particular job for which they are hired. Their mental, physical and moral qualifications should be studied and they should be assigned to work in view of the qualifications which they are found to possess.

When employed there should be every certainty that they are not to be discharged without due cause. If a man proves unfit for the work to which he is assigned, an effort should be made to find other work in the establishment for which he is qualified. Every employee should feel assured that the management proposes to keep him at work during good behavior if it is possible to do so.

In this matter of hiring and discharge, it is not safe to trust the foremen unless they are carefully supervised. There is no doubt that one of the most serious needs in our industries is a better education of the foremen and like subordinate officials and such supervision that they are unable to make the mistakes and do the harm that the wrong men can easily do in such positions.

Experience seems to show that one of the greatest economies that can be practiced in an establishment of fairly large size is the organization of a department which shall be devoted to the hiring, placing and discharge of men on definite and scientific principles. Moreover, if workmen feel secure in their jobs, except for their own definite failure to do good work, they must inevitably have a greater feeling of content and a stronger inclination to serve well the employer who has given evidence that he proposes to continue them in his employ.

That stability of employment is a matter of the utmost consequence to the employer as well as to the employee, is illustrated by the fact that not infrequently the management of an establishment finds that it must hire a thousand or more men really to add two hundred to its force. The cost of hiring and training all these men is a severe burden on industry.

In this same connection it is also clear that the management of our industries should give far more attention than is given at the present time to reducing irregularity of employment. To this end much may be done in each individual establishment by way of spreading out the work and declining to go to extremes in pushing production in good times and reducing it when the market is bad. If employers as a whole were to take up the problem seriously and endeavor to work together for its solution, there is no doubt that cyclical as well as seasonal extremes of undue activity and undue depression could be to a large extent minimized.

Such schemes as profit sharing, bonus payments, the acquisition of stock by the employees and other devices for increasing the return to the wage earner are worthy of careful consideration; but in each case in view only of the conditions of the particular establishment. It may well be that in some instances the management may determine that one or the other of these plans is likely to give to the workmen a more permanent interest in the enterprise and therefore to remove antagonism and develop loyalty.

## WAGES AND WHAT SHOULD DETERMINE THEM

It seems probable, however, that the workmen for the most part are chiefly interested in the pay which they receive at stated intervals. While they should be encouraged to save and make investments, it may well be that in most cases they would not be greatly influenced by the chance of return at some period which seems to them remote.

While there is no doubt that the law of supply and demand will always, to a large extent, control in the matter of fixing wages, those engaged in industry are, I think, becoming more and more convinced that as a practical matter the operation of this law may well be modified in view of other considerations. In a normal industry each workman should surely be able to earn enough to live comfortably in accordance with the standards of a right-minded man of his position in life, and to save for a rainy day and for old age. If he cannot earn as much as this, he should not remain in that industry. If the industry cannot pay the normal workman this amount, it should not, in the long run, survive. It moreover seems clear that efficiency and loyalty should be recognized in the wages paid; also that the wages might well to some extent reflect the prosperity of the individual establishment.

In this matter also the burden is upon the management of each individual establishment to deal fairly and justly with its workmen in view of the conditions characterizing that establishment; but it is certain that more satisfactory results will be attained if consideration is given to the ideas of its workmen on the subject and an effort is made to make them understand why the wages proposed or paid are reasonable and proper.

So as to hours of work. There can be no possible reason for a fixed period for all industries. In each it should be determined by scientific study what number of hours a day will make possible the maximum production consistent with the health and reasonable comfort of the workmen. Even in the same industry the hours of work may well vary in different establishments. The locality, climate, general environment and living conditions are important factors in determining how long one may work without sacrifice of health or comfort. There is no comparison in this regard between, for example, the conditions of men in a shoe factory in the country and those similarly employed in a shop in the heart of a city like St. Louis.

Here again the solution of the problem is one for the individual establishment, to be determined by the management, preferably after conference with the employees who are very likely to assent to a sound conclusion when the conditions are fully explained to them.

There seems to be no doubt that overtime work under present conditions cannot be justified except in the case of a real emergency. As we all know, overtime work is insisted upon by many employees as a device for getting a larger return for their services. This is mere pretence, overtime being used as a plausible camouflage for an unstable and deceptive situation.

Much might be said as to the spirit of our institutions and how inconsistent with that spirit would be the domination of the industries by the labor unions; while, on the other hand, the "open shop" and the personal dignity of the relations between employer and employee, which is reflected in the "open shop," illustrate perfectly the principles of individual freedom and of fair play which are at the basis of our economic as well as of our political and social life.

## EMPLOYERS MUST DEAL OPENLY AND FRANKLY WITH THEIR WORKMEN

If I am right in my views, the opportunity for bringing about a satisfactory feeling between employers and employees, by definite and conscious effort on the part of the management in the individual shops, is so great that it seems to be the plain duty of every individual employer throughout the country to adopt the principle of dealing openly and frankly with his workmen in all matters which need to be understood on both sides if relations are to be cordial.

Management can never be asked to sacrifice its function of

judgment and direction. If the so-called "democratization of industry" means the contrary of this, it is nonsense. The workmen would be the very first to recognize that ultimate control must be with the employer. Naturally, however, they cannot be satisfied if no opportunity is given them to state their point of view as to matters which are of the utmost importance to them in their life's work.

It is obvious that such relations as should exist between management and workmen are only possible in an establishment which is not tied up with the trade or labor unions. There alone are the workmen free from outside influence, which may be and often is used to stimulate antagonism and to breed dissatisfaction as well as to reduce efficiency.

## EFFICIENCY AND PRODUCTIVE POWER GREATER IN THE OPEN SHOP

In the "closed shop" it is in effect the labor union which negotiates with the employer as to wages, hours of labor and working conditions and its negotiations are carried on from the point of view of the labor union and not of the men; although even in a "closed shop," under some conditions, "shop councils" or meetings between the management and the employees would be possible. There are not, however, likely to be such relations in the "closed shop," particularly as the American Federation of Labor, at its annual convention in 1919, definitely resolved that "we disapprove and condemn all such company unions [works councils, etc.] and advise our membership to have nothing to do with them." The resolution further stated that "we demand the right to bargain collectively through the only kind of organization fitted for this purpose, the trade union." In the steel strike the "abolition of the company unions" was one of the fundamental demands of those promoting the strike.

It seems incredible that the people of this country, as a whole, if they really understood the situation, should not stand firmly for the "open shop," as distinguished from the "closed shop," not only because of the greater efficiency and productive power of men who are not bound by union rules but also because, in the "closed shop," personal and direct relations between employer and employee without outside interference are practically impossible.

Of course, an employer should be free to allow his shop to be organized and to deal with the trade unions, as representing his men, if he is willing so to do, just as he should have the right to work through a closed non-union shop; but certainly there should be no moral pressure brought upon him to force such action on his part.

There are many other questions which some regard as of great importance in relation to the present labor conditions. For example, how far if at all should the state interfere by the compulsory arbitration or by way of conciliation and mediation in labor difficulties? Something of the sort must come if labor-union domination is to characterize the future of industry.

On the other hand, if the development is on such lines that the employer and employee in each individual establishment take up in a sane fashion the problem of fixing the employment relations on a fair basis, it may well be that labor difficulties will be so reduced that no scheme of arbitration or conciliation would be worth while. Certainly, no one can look forward without perturbation to the interference of such boards. Experience has shown their incapacity and the unsatisfactory results of their efforts.

Another matter which would be of vital importance if labor-union domination were to prevail would be assurance of the responsibility of the unions and of their legal obligation to carry out the agreements that they make.

At the present time the labor unions are practically immune against attack even for their crimes. They are not clearly responsible to those whom they unlawfully injure. They may not be held on the contracts that they make. Their compliance with an agreement is almost altogether a purely voluntary act on their part. If they were to become the representatives of the men and were to act for the men in a substantial part of the

# Systems for Mutual Control of Industry

By WILLIAM L. LEISERSON, ROCHESTER, N. Y.

IT is difficult for us to change our conception of those conditions and relations as we have learned to know them in years of experience, said Dr. Leiserson, in introducing his discussion of shop committees, works councils and the cooperative or industrial democracy plans by which employers propose to give their employees some voice in the control of industry, as contrasted with trade-union collective bargaining by which organized wage earners attempt to force employers into a system of joint control of wages and working conditions.

"This is particularly true," he continued, "of conditions of employment and the relationship between employer and employee." He pointed out that the world war and the shortage of labor since the armistice was signed have materially changed the status of the employee, and that however much the employer may realize the changed industrial conditions he finds it immensely difficult to conceive of his employees as people who do not have to obey his orders, but instead have to be consulted in any action that may affect them.

"To talk about mutual or democratic control of industry or to establish plans for cooperative or industrial democracy without a clear realization of the revolution that has taken place in the status of the wage earner can lead only to confusion and to failure of the plans for mutual control of industry," Dr. Leiserson asserted. He then compared the present situation with that in the fourteenth century in Europe when an industrial revolution brought on by the Black Plague and characterized by much the same industrial ills that we suffer now, resulted in changing the status of the laborer from that of a serf to a wage earner. He then traced the history of the labor movement in this and other countries, covering much the same ground as in his former address, published in the November 1919 number of MECHANICAL ENGINEERING, p. 884, and continued: "In a democratic country with rising standards of living and large numbers in what we call the middle classes there is no great danger of labor completely dominating the situation and becoming the only masters of industry. But just because we are a democratic country with rising standards of living, and because our wage earners are now approaching the status of members of the middle class, we cannot permit employers alone to remain the masters of industry as they

have been in the past. There is more danger of Bolshevism from the employers' side in this country than from the workers' side. Dictatorship by the plutocrat is worst than dictatorship by the proletariat. We are warned against the latter and the people of the United States will never permit wage earners to take over our industries and control them absolutely. But we are not warned against the employer doing the very same thing and there

is great danger that in our fear of Russian Bolshevism we will be led to side with those employers who attempt to fortify themselves in their old positions of sole and only masters and dictators of industry. Only the public through its regularly constituted government can be permitted to be masters of industry. Both employers and employees must be servants of the public. The mistake we are likely to make in dealing with this problem is to assume that because industrial democracy necessarily involves an organized labor force capable of acting as a unit through its representatives, therefore every organization of working people in industrial plants is an example of industrial democracy. As a matter of fact, however, a study of the employees' organizations now in existence will show that they classify themselves into three general groups and that the element of democracy is present in only two of these groups, but not to the same extent in each.

## EMPLOYEES' ORGANIZATIONS

"The first group of employees' organization plans may be called shop committees proper. These are merely advisory organizations of the working force selected either by the management or by the employees for the purpose of conferring with the foreman, with safety directors or personnel and service managers regarding various problems related to working conditions in the plants. The matters with which these committees are concerned are primarily safety and welfare work with a small number trying to extend their activities to include grievances. Although these committees

are constantly hailed as examples of industrial democracy, they involve no element of collective bargaining or joint control over terms and conditions of employment. Complete authority is centered in the management, the committees merely giving advice and suggestions which may or may not be accepted by the management. The powers, functions and methods of operation of these committees identify them with the service work of the plants rather than with problems of bargaining, of wages, hours and shop discipline.

"The second group of organizations may be called 'employers'

*"In a democratic country with rising standards of living and large numbers in what we call the middle classes there is no great danger of labor completely dominating the situation and becoming the only masters of industry. But just because we are a democratic country with rising standards of living, and because our wage-earners are now approaching the status of members of the middle class, we cannot permit employers alone to remain the masters of industry as they have been in the past."*

*"Labor management means control, discipline, an industrial organization held together by rules, orders and authority, reaching down from an executive head at the top. Collective bargaining implies a questioning of that authority. It is based on the principle that an individual employee cannot effectively question the authority of the management. It says there must be no rules or orders affecting the lives and welfare of the wage-earners without the consent of those who must obey them."*

*"Here we have the age-long problem of reconciling authority with democracy. Law, order, government, we must have in industry as in all other human institutions, but the day of autocratic control is gone, at least in all western civilizations. To maintain law, order and government in the industries of these western countries there must also be democracy, the consent of the governed. Without such consent, without such democracy, our industrial governors find themselves unable to control their organizations, to have their laws, rules, regulations and orders obeyed. This is the essence of the industrial problem today."*

WILLIAM L. LEISERSON.

(Chairman, Labor Adjustment Board.

Presented at the Annual Meeting, New York, December 2 to 5, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in slightly abridged form. All papers are subject to revision.

unions.' In this group are included all those plans which either explicitly say, as does the Midvale Steel and Ordnance Company plan, 'We recognize the right of wage earners to bargain collectively with their employers . . . ' or which by implication recognize the principle of collective bargaining as do the plans of the Bethlehem Steel Company, the International Harvester Company and the Colorado Fuel and Iron Company. The employees' organizations in this group represent a long step in the direction of industrial democracy, for they involve getting the consent of the employees who are the governed in industry, in the making of industrial laws. As political democracy provides for the consent of the governed in the state, so industrial democracy will provide for the consent of the governed in industry. The difference between these 'employers' unions' and the ordinary unions known as 'organized labor' is that the former are initiated by the employers; they are confined to one company rather than connected with a national organization of employees and the management is not excluded from the meetings.

"The third group of organized workers are the ordinary labor unions, and they usually involve written or understood agreements between national unions of the employees and individual firms or associations of employers. The agreements invariably cover wages and hours and usually working conditions as well. The Hart, Schaffner & Marx plan and the contracts of a number of firms in Rochester with the Amalgamated Clothing Workers are examples of agreements with individual plants, while the conventions of the United Mine Workers and Coal Operators, and the Joint Boards of Control in the needle trades in New York City may be cited as examples of agreements with associations of employers.

"However much the employer whose workers are included in the third group may object to the principle of collective bargaining, he understands thoroughly that his agreement with the union involves that principle. In the second group, however, in the plans we have called 'employers' unions,' there is not always this clear understanding on the part of the employer of what his employees' organization involves. Where the principle of collective bargaining is present only by implication as is true in practically all the plans except that of the Midvale Steel Company, it quite often happens that the employer does not realize that his plan involves this principle. The employees, however, usually assume it does not mean anything unless it gives them the opportunity to bargain collectively with their employers. It is hardly necessary to point out that any misunderstanding like this of the purposes of a plan of employee representation is likely to cause trouble between employer and employee."

#### COLLECTIVE BARGAINING WITH ORGANIZED LABOR

Dr. Leiserson then discussed the features of collective bargaining which he believed would contribute to its success, and those which would doom it to failure. He contended that the vast majority of such dealings between employers and employees must be carried on by organized labor for the reason that organized labor is growing very much faster and stronger than the competing movement of company organizations launched by the employers. "During the past four years," he said, "when the works council movement has made such great headway, very many more wage earners have joined the regular organized labor movement than are included in all the company plans put together." Also, that inasmuch as there can be no permanent raising of the status of the wage earners unless the whole industry is affected, "there can be no effective bargaining, particularly in a competitive industry, unless it be conducted on a national scale."

"Works councils, or a union confined to one plant or a few plants, can do little to give to the wage earner a larger share of the returns from industry as compared with what capital and management has been receiving. And this is what collective bargaining and democracy in industry aims at.

Competitive conditions will hold the single plants down to

the level of the industry as a whole. Before the distribution of wealth produced by industry can be improved to give labor a larger share, collective bargaining on a national scale covering all markets, must be established. It is because the wage earner sees this that he is so easily led away from company unions by a national organizer.

"Labor management means control, discipline, an industrial organization held together by rules, orders and authority, reaching down from an executive head at the top. Collective bargaining implies a questioning of that authority. It is based on the principle that an individual employee cannot effectively question the authority of the management. It says there must be no rules or orders affecting the lives and welfare of the wage earners without the consent of those who must obey them. It joins the members of the industrial organization into a union and forms a democratic legislative body for the purpose of giving to those who have to obey the laws of industry a voice in determining what those laws shall be. Labor management implies power, authority or lawmaking in the hands of the employer. Collective bargaining means democratic representation in the process of that law making and democratic control of the exercise of that industrial power or authority.

"Here we have the age-long problem of reconciling authority with democracy. Law, order, government, we must have in industry as in all other human institutions, but the day of autocratic control is gone, at least in all western civilizations. To maintain law, order and government in the industries of these western countries there must also be democracy, the consent of the governed. Without such consent, without such democracy, our industrial governors find themselves unable to control their organizations, to have their laws, rules, regulations and orders obeyed. This is the essence of the industrial problem today."

#### AN ATTEMPT TO SECURE DEMOCRACY AND EFFICIENCY IN THE CLOTHING INDUSTRY

Dr. Leiserson then described an industry where an attempt has been made to put labor relations on a democratic and efficient basis, where collective bargaining with a Union prevails, and where the administrative machinery necessary to make collective bargaining work satisfactorily, has been created. This is the clothing industry, which employs over 200,000 people. It has four great market centers, New York, Chicago, Rochester and Baltimore. In all of these markets it is now almost completely organized and only a few firms are outside the agreement between the Clothing Workers Union and the employers' associations.

Dr. Leiserson said that both sides are organized, and that there can be no real collective bargaining if only the workers are organized and enforce their will on the employers, any more than when only the employers are organized. "In each of those cities," he said, "there is an agreement between the Employers Association and the local branches of the union. The agreements fix minimum wages; establish a working week of forty-four hours, provide for open or preferential shops, except with one association which granted a closed shop, prohibits strikes, and restricts the employer's rights to discharge by making him give a good reason for every dismissal.

"The local unions of the various trades in the industry elect delegates to a central body, known as a Joint Board. This board employs managers and deputies whose business it is to represent the employees in handling their grievances. In each shop the employees also elect representatives called Section Chairman and Shop Chairman.

"On the employers' side there is a similar organization. Each of the large plants employ a labor manager, who has charge of all bargaining and labor control, as well as employment and service functions. For the smaller plants, the employers' association employ labor managers who perform the same duties for groups of employers. In New York and Chicago, there is a chief labor manager employed by the association, and all the

# What May We Expect of Profit Sharing in Industry?

By RALPH E. HEILMAN,<sup>1</sup> CHICAGO, ILL.

**T**HAT the subject of profit sharing is not one which is new to this country but dates back to the early 70's when there was a very widespread interest in the whole subject of profit sharing, was pointed out by Dean Heilman. Many experiments were introduced at that time and profit sharing was heralded as if a panacea for all industrial problems. Most of these experiments were soon abandoned, however, and profit sharing came to be regarded as a subject of interest mainly to the social reformer or theorist and of little interest to the business man. In the last few years, however, there has been a marked increase in the attention paid to the subject, which justifies a reexamination of the profit-sharing plan in the light of modern business practice and methods.

## WHAT CONSTITUTES PROFIT SHARING

"At the outset," said Dean Heilman, "let us ask ourselves in what really consists profit sharing, because as a matter of fact there are many plans widely heralded throughout the country as profit-sharing plans, which do not, in any real sense, embody the fundamental principles of 'profit sharing.'"

"Profit sharing is an agreement between an employer and his employees whereby the latter participate in some way in the profits of the business, either of the business as a whole or of some unit part of the business. This participation is on a predetermined basis definitely known and established. With that conception of profit sharing in mind, the question is asked, 'Why should any employer, firm, or corporation wish to introduce an arrangement of this kind and voluntarily share a portion of its profits with its employees?' Continuing, the speaker discussed the various aspects of profit sharing as a business arrangement, and said in part:

"The typical wage earner seeks neither philanthropy nor charity, and likewise the employer does not wish to distribute gratuities to his employees. Therefore, if profit sharing is to justify itself, and to be introduced on any wide scale, it must be as a business arrangement which will prove mutually advantageous and profitable, both to the employer and employees.

## BUSINESS REASONS FOR INSTALLING A PROFIT-SHARING SYSTEM

"What, then, are the business reasons which would lead a firm to introduce this profit-sharing system and what are the advantages which its introduction would bring about? In the first place, it is claimed that profit sharing will increase efficiency and output.

"But only to a certain extent is this true, and only under special circumstances and subject to special limitations; in other words, generally speaking, more effective results are obtained from labor if compensation is on the basis of the measurable results of each individual so that he will be induced to put forth his best efforts. It is frequently difficult, if not impossible, however, to ascertain and apportion the results of the individual worker, since there are conditions under which labor presents a joint product, in which it is impossible to compute or disentangle one individual's work from the mass production of all the workers.

"Under these circumstances profit sharing may prove desirable and prove an additional incentive to increase production far in excess of what would be secured with the flat hourly rate. For example, consider the Procter & Gamble plant at Cincinnati,

which for 20 years has had a thoroughly successful profit-sharing plan in effect. Here the men are engaged in shifts, keeping the huge vats of soap in continuous operation, so that it would be impossible to separate the work of one shift from that of another and award any one shift over and above another.

"The same is true in most lines of work in the gas industry, which probably accounts for the fact that in England profit sharing is in vogue in connection with some of the gas plants in that country. Where work can be definitely measured, the best plan, probably, is to pay the individual on a basis of individual results. But where work cannot be definitely measured, then the profit-sharing plan may prove an effective supplement or addition to the regular flat-time wage.

"Secondly, profit sharing may be introduced for the primary purpose of promoting permanency and stability among the employed staff and as a consequence reduce the labor turnover. Ordinarily reliance is placed on what may be called two 'deferred features' to accomplish this result. The first of these is the preliminary or qualifying period which an employee is required to serve before he can participate in the profits. This may be six months, or two years as in the plant of the Dennison Manufacturing Company, or three years as in the case of the Burt plant, or seven years as in the case of the Sears, Roebuck & Company plant. Reliance is placed on this qualifying period to hold the employee until its expiration so that he may qualify to share in the profits.

"The second deferred feature is that the profits are only to be issued at stated periods, say, once in six months, or at the end of the year, with the proviso that if the employee leaves the service of the company before the profits are distributed, he foregoes his participation in the profits. Reliance is placed on this feature to hold the employee until the end of each period.

"The power of profit sharing to hold employees and promote stability of employment depends on the question as to whether the profits paid represent a net addition to the full current-market wage paid to similar classes of workers in other industries. If profit sharing is used to depress wages the employees would not desire to accept the profit-sharing plan, and it would defeat itself in that way; but if the profits to be paid represent a net addition to the going current-market wage, it has been demonstrated that in many cases the introduction of profit sharing will tend to reduce the labor turnover and promote permanency and stability among employees.

"Again, profit sharing is sometimes introduced with the hope that it will promote industrial peace, that it will do away with industrial strife, industrial disputes and strikes, and that thereby a larger degree of wholesome and cordial industrial relations will be promoted between employer and employee. Profit sharing has possibilities in this direction, but they have been exaggerated. It is significant that profit sharing is not now, and never has been, one of the demands for which organized labor has striven, and that in some instances strikes have immediately followed the introduction of profit sharing. Instead of giving an ironclad guarantee to industrial peace, profit sharing may give rise to new causes of controversy, as for example, controversy over the percentage or amount of profits which should be shared, or the method by which it should be computed.

"Nevertheless, under certain circumstances profit sharing may be expected to promote wholesome industrial relations, but if it is to be introduced for this purpose the most promising and fruitful field for its application is in those plants which have already introduced so-called shop committees, or internal unions of employees, or works councils. For here any degree of management sharing which is accorded to the employees may go hand in hand with profit sharing, the one strengthening and reinforcing

<sup>1</sup>Dean, School of Commerce, Northwestern University.

Abstract of an address presented at the Annual Meeting, New York, December 1919 of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

the other, promoting a better understanding and a more wholesome, cordial and peaceful relations.

#### VALUE OF PROFIT SHARING IN PROMOTING EFFECTIVE MANAGEMENT

The most important purpose for which profit sharing has been introduced, in the opinion of Dean Heilman, is to promote effective management upon the part of managerial executives, semi-executives, junior executives, and salaried employees all the way from foremen or sub-foremen up. Although the great bulk of the literature on profit sharing deals with its applicability to the rank and file of the wage-earning group, the most promising and fruitful field for the application of profit sharing rests with the salaried class, those holding the positions of larger importance and larger responsibility in business. People of this character ordinarily are paid a flat salary, because so far we have evolved no other satisfactory method of compensating this class of workers, but we are beginning to realize the inadequacy of a flat salary even for those who hold executive, semi-executive, or minor executive positions. The flat salary usually fails to draw forth from a man the best exercise of his abilities, and it is not always the case that salaried employees find incentive through the hope of advances do not come as fast as expected, or when the salary limit for the job is reached, there develops a lassitude, and often a lurking resentment in the back of the employee's mind which mars his efficiency.

One of the most important questions at the present time is how best to compensate those hired to manage an industry, because at the present time, in larger-scale industries, even those who occupy most important managerial places, are to a very considerable extent hired employees. A partial answer to this question, according to the judgment of the speaker, lies in the application of profit-sharing schemes or restricted profit-sharing schemes, especially for those who occupy the positions of larger importance and larger responsibility in these business organizations. Dean Heilman said:

"This principle has already been recognized by a considerable number of business organizations. Two organizations which have successful profit-sharing plans, limited to the small upper group, are the Denison Manufacturing Company, which includes about 200 employees out of a total of 3,000, and the Solvay Process Company, which divides the executive heads of its department into three groups according to their responsibilities. Then there is the plan of the Studebaker Company, grouping the employees into four groups, in direct ratio to their responsibility and classification. The same thing is true of the Dold Packing Company, which has its executives classified in two groups. A number of other companies might be mentioned which have their managerial employees classified into groups for profit-sharing purposes.

"This principle has been applied by the largest department and merchandizing establishments in the country to the department heads—in the latter case, the special or additional compensation generally takes the form of a percentage, not of the total operations of the business as a whole, but a percentage of the profits simply of the particular department of which the individual happens to be in charge.

#### EFFECTIVENESS OF PROFIT SHARING AS AN EFFICIENCY DEVICE

"The most important conclusion in this whole subject is that effectiveness of profit sharing viewed simply as an efficiency device and peace arrangement for the purpose of increasing profits by sharing them, is in direct ratio to the rank of the participants and in inverse ratio to the size of the participating group. Stated in another way, the effectiveness of profit sharing purely as an efficiency arrangement is greatest among large groups, or if applied to the rank and file of wage earners, is greatest among small groups.

"What is the relation," asked the speaker, "of the effectiveness of profit sharing to the rank or responsibility of the participant? In the first place, the higher the rank, the greater is the oppor-

tunity which the individual has to exercise an important influence on profits. A purchasing agent, for example, by one shrewd purchase, can exercise a greater influence on the total profits of the business than a workman in the course of a year, no matter how faithful he may be in the performance of his duties.

"In the second place, the greater the responsibility, the easier it is for the employee to see the relation of his efforts to the profits of the business. It is easy for the sales manager to see that if he finds a new market for the product of the concern, he will thus increase profits. But it is a difficult thing for the elevator man to see that he can so run his elevator that he can produce any great increase in profit.

"In the third place the managerial or executive group are more familiar with business vicissitudes and uncertainties than the rank and file. This has an important effect when you come to a lean year. Many profit-sharing plans have gone on the rocks when they have struck a lean year. When the profits are small or non-existent, it often happens that the employee who has worked as hard as he did the previous year is suspicious that some advantage has been taken to deprive him of his portion of the profits. But in the case of the managerial employee he has foreseen the conditions, is familiar with the market conditions and market fluctuations, and instead of losing confidence in the profit-sharing plan, he may gain a larger sense of partnership in the enterprise.

"What is the relation between the effectiveness of the scheme and the size of the participating group? It would seem that a profit-sharing plan would operate successfully for the rank and file of wage earners only when applied in a small or medium-sized shop, because the larger the group of participants, the more difficult it is to educate them in the essentials of profit sharing, and the larger the group, the less effect each one can exercise on profits.

"These conclusions are verified by the history of profit sharing. In nearly every scheme of profit sharing for the wage earner which has been abandoned, it will be found that it was a scheme which included a large number of the rank and file indiscriminately. Also many plans have been abandoned so far as the rank and file are concerned, but retained so far as the managerial and salaried group are concerned. Moreover, although many of the profit-sharing plans introduced for the benefit of the managerial group have been modified, none, so far as I know, have been abandoned as failures.

"Profit sharing is not a social panacea," concluded Dean Heilman. "It will not solve the vexing problems which arise between employer and employee. It will not prove a substitute for good management on the part of the corporation, nor will it prove a substitute for the wage system. But within the wage system it has a place, a real place. In my judgment, we are destined to see a much wider and a much wiser use of profit sharing than in the past."

Although the Bureau of Standards dropped most of its experimental work upon the use of metal to replace wood in airplane construction, the future of metal construction appears promising, especially as the need for a fire-resisting airplane becomes more generally understood. To avoid the difficulty which has been found in designing sheet metal parts so as to secure sufficient compressive strength one engineer has devoted much time and study to the use of steel tubes. A single metal tube has much less strength for its weight than a beam designed to concentrate most of the material in the flanges which are subjected to the higher stresses. The tubular design uses several small cold-drawn steel tubes for the flanges which are connected by diagonal latching of tubes of the smaller diameter. It is also possible to join tubes by inserting a snugly fitting tube of smaller diameter into another for a distance which will give satisfactory strength. Methods of fastening the two tubes together readily present themselves. It is believed that encouragement and assistance given to metal construction by this Bureau is now about to result in material improvements which will come into general use.

# The Future of Aviation

Landing Fields and Wireless "Beacons" the Great Need—New Inventions Less Important—Future Wars will See Armored Planes and Aerial Torpedoes

By COL. E. A. DEEDS, DAYTON, OHIO

ON Thursday evening, December 4, at the Annual Meeting of The American Society of Mechanical Engineers, the night when the members of the Society and their friends gather for their annual reunion and lecture, Col. E. A. Deeds, the first speaker of the evening, was greeted by a large audience, to which he presented in a most entertaining manner some of the possibilities of the future of aviation both for military purposes and in its commercial applications. Following Colonel Deeds, Col. Thurman H. Bane, Chief of Engineering, Division of Air Service, and commanding officer of McCook Field, displayed a series of lantern slides and moving-picture films of McCook Field and the work accomplished there. These pictures were released by the War Department for this lecture for the first time and a number of the views are reproduced in the engravings on the following pages. The remarks by Colonel Deeds are here given in abstract and present some of the most interesting facts which he brought out.

"When any one talks on the future of aviation we indulge in flights of the imagination and we measure his ability as a speaker by the number of thrills he can give us as he pictures the wonderful things which are likely to happen. This places one who knows the industry at a disadvantage because the great thrills of aviation have already taken place. I would rather, for instance, take up tonight the work of the Wrights and the beautiful story of how these two brothers worked together; how their savings were expended and how their sister readily gave hers, the experiences around the fireside, and the sacrifices made—a story which will never be duplicated. It is one of the finest examples of courage and originality, interwoven with family devotion and sacrifice, which will always stand as one of the great achievements of American invention.

"Then if we pass from the date when Orville Wright made his first flight in 1903 to the time of the war, we will find a struggling industry, many sacrifices, and here again, events that never will be duplicated.

"The war itself gave a tremendous impetus to aviation; and when we get enough perspective and are far enough removed from it so that the public will be able to discern between the patriotism and performance on one side, and propaganda and politics on the other side, there will be found a real record of achievement, more potent and more inspiring, probably, than anything the future can give us, at least for some years to come. The short period of the war gave aviation a greater impetus than it would have received from fifty years of old peace-time experiences along these lines. There was created during that time an organization out of nothing, practically, that provided 16,852 airplanes, 40,420 engines, 642 balloons, several hundred flying boats and many accessories that had to go with them—a tremendous undertaking, and accomplished with fairly good success.

"There were such accessories as the wireless telephone, the oxygen apparatus, so that the aviator could breathe at high altitudes, the bombs that went on the planes, the gun sights, the electrically heated clothing, machine guns, fixed guns, synchronized guns, 37,000 of which were provided, the pyrotechnic accessories that went with the airplanes, the instruments of navigation and others which created an industry in which there were approximately 300 concerns involved, and over 250,000 men working on apparatus for the Air Service when the armistice was signed.

"Along with this development came the need for supplies—the demand for raw material. There was particularly a large demand for spruce timber. There were 27,000 or more boys in

uniform out on the coast who were engaged in supplying the Allies with spruce for the building of airplanes, and because of their activities we were never compelled to shut down a single factory in this country or abroad, because these men supplied all the lumber that was required. The chemical industries supplied the dope that went on the wings, oil, and things of that sort, and there is a long list of industries which furnished material and supplies to advance the work.

"During these eighteen strenuous months there were developed and produced 15,576 Liberty engines, representing a total of more than 6,000,000 hp., an accomplishment which history unquestionably will put down some day as one of the great mechanical achievements of the war. The Liberty engine was the first across the Atlantic, the first across the Continent, and by the sheer force of its inherent merit, it has put itself among the foremost engines of the world. It was a great accomplishment, done with great credit to the manufacturers, who cooperated in a wonderful way to make that work successful."

Colonel Deeds spoke about what the boys themselves did, stating that twenty-two thousand were trained to fly in this country, and they flew approximately 66,000,000 miles in their training alone, with the splendid record of only one fatality to every 200,000 miles, or the equivalent of eight times around the earth. This is an indication of the comparative safety of this form of transportation. That thousands of boys from all parts of the country, brought into camp under military discipline, should go through the most perilous part of flying, that of training, with the loss of only one flier in a distance which is equivalent to flying eight times around the world, is an achievement to be proud of. With regard to the record of the boys in France, he said: "The knights of old cannot picture anything more dramatic than the young men who went out in these powerful machines, going out alone, going up 10,000 or 15,000 ft. out over the enemy lines, and meeting in hand-to-hand combat, as it were, the enemy. Never will a page be written in history that is as brilliant and thrilling, because in future wars we will look on these things more as a matter of course, even though they will take a more important part.

"There has been during this war period a record of accomplishment which is more potent and more inspiring in many phases than anything the future can give us for a long time. That does not mean, however, that there is not a great future for our aviation. But it is going to have this disadvantage, that it will be misunderstood and partially discredited by the public. Because the airplane has not accomplished all the spectacular feats which were prophesied for it, the public is now inclined to underrate the possibilities of aviation. Too much credence should not be given to those who picture the air full of airplanes on various missions, moving on our hotels in flocks, surrounding our office buildings, and carrying passengers to their occupations. The future of aviation is bright enough viewed from a practicable standpoint."

Looking to the future the speaker predicted that the line of development in military aviation will take several forms. There will be armored airplanes, protecting the pilot and observer, and limited, of course, in size and thickness of armor, which will be made of more highly specialized and better-treated steel. Larger planes should be developed, planes carrying cannon and more guns, so that there will be no blind angle. These planes would not maneuver, but go directly to their objective. The ground-strafting machine, armored beneath, with machine guns pointed down to cover the trenches, will undoubtedly create havoc.

The ability to reach high altitudes is another line of develop-

<sup>1</sup> Chief of Equipment Division of Air Service during the early development of the air program of the war. *Mem. Am. Soc. M. E.*

ment that is vital because, as Colonel Deeds put it, "About the only safe place in this game is to be up where the other fellow cannot get." That means that the air fighters of the future will have to be able to do their work at an elevation of 40,000 ft., in a temperature 50 deg. below zero.

Then, higher speeds will be necessary. Approximately 160 miles is the maximum speed today, not the advertised speed, but the speed.

There is also the aerial torpedo, that is, the pilotless aeroplane, that will go out 100 miles and then shed its wings and drop the whole fuselage, accurately hitting a target the size of a city.

"That," said the speaker, "is not a dream, and the problem was so well developed during this last war that there was a group of young men who were sorely disappointed when the armistice was signed, because they had expected to go over and discharge these pilotless machines against the enemy and create havoc in his ranks." That is a line of development which is sure to come.

There is the possibility of wireless control, too, but it has many difficulties, and may not be practicable.

The line of tactics that ought to be used by the military aviation division is a very important thing, and involves better communication, better relationship with other branches of the Army, the independent work to be done by the aircraft—a whole new line of work just touched upon by the war which must be interwoven now with our military tactics in every way. This can be done only by thorough, painstaking, experimental and development work. It is going to require the services of the engineer in the laboratory and of the flier in the field. Time, the greatest element in all of these undertakings, the thing we could not get in this last war, will be required to put this future aviation where it belongs in this country; that is, time enough for these engineers to do their work.

After outlining these various lines of development in military aviation, Colonel Deeds took up the subject of commercial aviation and said in part:

"At the present time the risks are too great, and the expenses too high, for private capital to go into commercial aviation. Government aid must be injected in some way into the commercial side of our aviation, if any progress is to be made. The worst thing that could happen to commercial aviation would be to place the entire responsibility upon the Government, but there ought to be some way worked out whereby moderate sums would be appropriated each year, to assist the commercial side of this industry until such a time as it can take care of itself.

"The most important thing for commercial aviation today is the simple thing of landing fields, because until we get them we can have no so-called commercial aviation. Municipalities should set aside certain grounds for this purpose and the Government should in some appropriate way assist the municipalities so that they can give these fields. The future should find every city of 10,000 inhabitants with these landing fields.

"Secondly, we need wireless beacons or lighthouses, as it were, scattered over the country, and placed with just as much care as we exercise in the case of our lighthouses for our water navigation.

"There is no reason at all, from an engineering standpoint, why we cannot have dotted over this country, at landing fields, and at frequent intervals, little wireless signal towers that will give out a proper signal, and enable the aviator to fly across this country and run no danger of being lost.

"We also need various instruments of navigation. We have not a compass upon which we can entirely depend. The gyro compass, or something of that kind, must be developed. We also need drift instruments, so that the aviator may fly straight in one direction without being carried off to one side. These are some of the practical, simple things that have to be done to make aviation safe. Commercial aviation will follow, if we have landing fields, wireless lighthouses and the proper navigation instruments.

"In addition to landing fields, wireless lighthouses, and proper navigation instruments there are other less vital needs. There is the matter of meteorology. There has been given to us a third dimension—we must study the condition of air currents at the

highest altitudes and make maps that can be used for aerial navigation, a work which the Weather Bureau might well be handling now. Exploration of higher altitudes made during the War showed that 95 per cent of all the winds at an altitude above 10,000 ft. are from the west and east, both in this country and Europe. Explorations were made at 35,000 ft. and some as high as 60,000 ft. One interesting record was made at Chattanooga, November 5, 1918, where at 28,000 ft. there was found an air current of 154 miles an hour, which means this: that an airplane going 154 miles an hour would be standing still going one way, or it would be going at the rate of 308 miles an hour the other way.

"Among other things, licensing of pilots is vital, so that we get competent men in charge of the aircraft. The testing of machines, to be sure that we have proper machines going into the service, flying rules, and other regulations are important.

"The Post Office Department has greatly helped commercial aviation and it ought to be encouraged. The kind of service it requires, flying in all kinds of weather, under all conditions, is tending to develop more reliable engines for the airplanes. It is also securing data on the cost of operation which will be available to the commercial enterprises that are to follow.

"The designs of machines for commercial aviation will have to be changed. We have in the last two years devoted our energies in the direction of high speeds, quick maneuvering ability, and similar matters, but we should get down to lower landing speeds, more comfort, and enclosed airplanes. Our controls will be worked differently, and a number of other things will have to be changed, but none of these are very serious matters."

Colonel Deeds believes that the maximum size of the airplane, that is, the heavier-than-air craft for our commercial work, has been reached, unless we can get better landing facilities, and that the lighter-than-air type of aircraft will come into prominence for carrying the heavier loads.

The discovery and development of helium in this last War, which formerly was provided in the laboratory at the cost of \$1700 per cu. ft., but now is available for less than 20 cents and is conserved by the Government, takes out of the lighter-than-air craft the one great hazard of fire, and with that hazard out of the way, an entirely new era is opening up. The lighter loads and greater speeds will be left to the smaller airplanes, perhaps, and heavier loads to the airships and to flying boats, which probably will be larger and more seaworthy.

In speaking of his own experiences and those of Mr. Kettering in flying, Colonel Deeds stated that the time required to go by plane from Dayton to Detroit is 2 hours; to Indianapolis, 1 hour; to Cleveland, less than 2 hours; to Washington, 3 hours; to New York, 4 hours; and to Wichita, Kansas, 7 hours. In addition to the great saving of time, the experience of flying is delightful. Colonel Deeds said that he believes in the privately owned airplane, but that he is restricted in his flying by the lack of landing fields and proper safeguards. Regarding casualties in flying, he said: "If you will take a list of the men who pioneered the automobile development, you will find that there is a long casualty list of men who have given their lives to that industry, and we have not any more of a casualty list in the airplane industry than in the automobile industry at this time."

Airplane development will come as that of the automobile came, first as a pleasure proposition and later as a utility proposition. Manufacturers are turning out a good many planes a week that are sold to individual fliers, but they have not the proper facilities for travel. Operating expenses are high but development of the industry will correct these. If engineers and manufacturers get together and are assisted by the Government, the airplane, while it probably will never attain the same degree of prominence that the automobile has attained, will nevertheless take a very important place in commerce. Aviation as an industry deserves the confidence and support of the conservative men of the country.

"Aviation will not reach the heights of the imagination which some have had about it," Colonel Deeds concluded, "but it will become a permanent part of the life of the people, and the thing that this country can do is to put the practical side into this industry for all civilization."

# The Annual Meeting of the A. S. M. E.

Record Attendance of over 2100—Interest Centers on Committee Activities and Session on Industrial Unrest—Addresses on Aviation and Discussion of Valuation Problems Leading Features

ATTENDANCE at the Annual Meeting of The American Society of Mechanical Engineers found the Engineering Societies Building in holiday attire for the occasion, with the foyer on the first floor lavishly decorated with fir trees and palms and the other floors that were to be used appropriately arranged for the convenience of the Society's guests. Anticipating a large attendance, a Sub-Committee of the Committee on Meetings and Program, composed of local members having the social arrangements in charge, prepared to utilize all the available space in the building. Besides the Society's headquarters on the eleventh floor, the meeting rooms on the fifth and sixth floors and the auditorium were made use of, and on Thursday evening, the annual reunion night, members also gathered in the spacious foyer on the first floor. There are five public-meeting halls in the building, all of which were in use at times. The total attendance was 2116, of which 1346 were members and 770 guests, the largest at any meeting of the Society.

Although the convention nominally opened on Tuesday, December 2, many were present earlier for Council and committee meetings, Local Sections conferences, etc.; twenty-eight delegates were in attendance from the Local Sections of the Society.

There was widespread interest during the convention in the discussion upon the reports of the Aims and Organization Committee of the Society and the Joint Conference Committee of the Founder Societies, and in the conference of the Local Sections' delegates. A full account of these meetings will be found in Section Two of this number, with other matters of general interest pertaining to Society affairs.

Numerous committee meetings were also held, including those of the A. S. M. E. Power Test Codes and its Sub-Committee on General Instructions; Research Committee and its Sub-Committee on Fluid Meters; the Committee on Steel Roller Chains; the Committee on the Standardization of Shafting; and the Standardization Committee.

On the social side mention should be made in particular of the gathering at the ladies' reception and tea on Thursday afternoon, always one of the pleasantest occasions of the Annual Meeting.

The excursions to points of interest about the city were well attended, particularly that on Friday to the Curtiss aeroplane plant and flying field at Garden City where exhibition flights were given and special arrangements were made whereby members who so desired were able to undertake flights. As usual the meeting of representatives of student branches was held and following the convention on Friday evening there were numerous college reunions. An event of interest to many was an evening devoted to an account of the work of John Ericsson and Cornelius H. DeLaunier, the founder of the famous DeLaunier Iron Works, the occasion being the eightieth anniversary of the meeting of these two noted engineers and the thirtieth anniversary of their death. Several societies joined in these exercises.

## The President's Address and Reception

The formal opening was on Tuesday evening, when President Cooley gave his presidential address on the Society's activities and national scope of the work of the engineer, printed elsewhere in this number. Following his address, the announcement of the election of officers for the ensuing year was made as follows: *President*, Fred J. Miller; *Vice-Presidents*, E. C. Jones, R. H. Fernald and J. R. Allen; *Managers*, D. S. Kimball, L. E. Strohlman and E. F. Scott; *Treasurer*, William H. Wiley.

In introducing the President-elect, President Cooley said that he had had the kind of experience which in his opinion qualified a man to be the President of The American Society of Mechanical Engineers. For 20 years he was a journalist, since which time he had been engaged in the business of factory management, an

expert on factory management. He served for five years on the Council of this Society, and for four years as Trustee of the United Engineering Society. His work as Trustee of the United Engineering Society had to do with the reorganization of its finances and other features, but principally the work of reorganization. During the past year he has had made a survey of the machinery—the office machinery—of the Society, and he has advised with regard to the development of MECHANICAL ENGINEERING, the Journal of the Society. He also rendered very distinguished service in the cause of his country during the war.

In replying, Mr. Miller said he regarded his election primarily an invitation to do more work, rather than a recognition of his service, and as such he gladly accepted it. His acquaintance with the history and methods of the Society made him fully appreciate that what should be done during the coming year would not depend so much upon the President as upon his fellow-members, and he would therefore bespeak the aid and cooperation of all those who desired to see the Society grow in numbers and in influence, keeping step with the best spirit and progress of the age.

The next event on the program was the conferring of Honorary Membership upon M. Charles de Freminville, consulting engineer, Creusot Works, France.

James Hartness, past-president Am. Soc. M. E., introduced M. de Freminville, who, he said, "is an engineer in the finest sense, a gentleman who understands the human element as well as the elements of machinery. He comes from a family, from an environment that combines the technical training with the practical life, that combines the science with the practice."

"M. de Freminville was one of the pioneers in introducing the corridor trains in France, and coming out of his long experience in engineering he has rendered distinguished service in the great war."

At the time when the long-range gun was shelling Paris, Mr. Hartness visited M. de Freminville in his home and went with him for a walk about the city to see some of the effects of the bombardment, and of the bombs which dropped from the aeroplanes. The spirit which M. de Freminville displayed at that time when his home and family were in such great danger made a deep impression on Mr. Hartness.

"While we are honoring one of the world's first engineers," he said, "we are also honoring a man who typifies that noble French spirit that took possession of the souls of the French people in that fight from the very first, and inspired their soldiers to 'carry on.'"

In his address of acceptance, M. Charles de Freminville expressed his deep appreciation of the tribute paid to him by the Society. Reviewing the history of the cooperation of America and France in their common ideal of civilization, he referred to the sewing machine as "the first object lesson which France had received from America," and the Westinghouse air brake as a second example. In return the Mallet compounding devices for the steam locomotive had been adopted in America and France had produced a steel car, the design of which inspired American engineers in the design of the present American steel car. The first low-level station was built in Paris, and it served as a model to the American engineers in the design of similar stations in New York. Again, cooperation between the two countries in automobile development had been very marked.

M. de Freminville also referred to the efforts made in both countries for the conquest of the air. In this connection he said:

While we were witnessing in France the successful experiments of Farman, about 1907, the news spread that two Americans, the Wright Brothers, had already obtained success in far greater achievements. This was very welcome, and this time France seemed to be the proper field for development of aviation. Count de Lambert flew over Paris some time later on a machine which he believed was designed by the

Wright Brothers, and he was promptly surpassed by Biérot crossing the Channel between Calais and Dover on his own machine.

M. de Freminville spoke of the work of Frederick W. Taylor and of the efforts of Professor Le Châtelier to introduce scientific management in France. The French public, he added, look upon the name of Taylor as a symbol of the efficient spirit that prevails in America.

He concluded by expressing the hope that America and France might come in closer contact by increasing interchange of students between the two countries. This interchange, he noted, has been highly beneficial in the past and would contribute greatly in the future to help the American and French engineers to develop a closer and more intimate friendship.

Following these exercises announcement was made that Honorary Membership was later to be conferred, in France, upon M. Auguste Camille Edmond Rateau, Chairman Board of Directors, Rateau, Batsu and Smoot Company, France. Mr. F. R. Low was asked to outline the work of M. Rateau, which he did briefly, saying that he was a pioneer investigator in the field of the steam turbine and the turbo-compressor. He is author of basic tables and formulae for the flow of steam through orifices, and author of methods of calculation and design of steam turbines now in practically universal use. He is the designer of numerous types of helicoidal fans. He is the inventor of the mixed-pressure steam turbine, and president of his own shops, manufacturing turbines and turbo-compressors as well as other types of high-speed rotating machinery, employing several thousand workmen. He has recently been active in the field of turbine propulsion of battleships, and in connection with the world war was author of notable contributions to the study of ballistics as well as inventor of devices to increase the efficiency of aeroplanes.

## Business Meeting

President Mortimer E. Cooley called the business meeting together on Wednesday-morning and asked Ira H. Woolson to present the proposed amendments to the constitution. These were as follows:

C45 The Standing Committees of Administration of the Society shall be

Committee on Finance  
Committee on Meetings and Program  
Committee on Publication and Papers  
Committee on Membership  
Committee on Local Sections  
Committee on Professional Sections  
Committee on Constitution and By-Laws

There shall be other Standing Committees of the Society as the By-Laws provide and the Council approves. The appointment, organization, duties and terms of service of all Standing Committees shall be as the By-Laws provide. The Chairman of all Standing Committees shall have a seat in the Council of the Society, but no vote. The Secretary of the Society shall be the Secretary of each of the Standing Committees.

C49 Professional Committees. The Council shall have power to appoint, upon a recommendation of the Society at a general meeting, or upon its own initiative, such Professional Committees as it may deem desirable, to investigate, consider, and report upon subjects of engineering interest. Any proposed expenses of such committees must be authorized by the Council before they are incurred.

C50 The Society may approve or adopt any report, standard formula or recommended practice and may print the same in the Transactions. It shall, however, not approve any engineering or commercial enterprise. It shall not consent to the use of its name or initials in any commercial work or business, except to indicate conformity with its standards or recommended practices.

C46 (TO BE ELIMINATED. SUPERSEDED BY C50 ABOVE.)

C51 Each Committee shall perform the duties required of it in the By-Laws, or assigned to it by the Council. Membership on the Council or any committee of the Society shall terminate automatically on account of absence of any member, either willful, or due to force of circumstances, as provided in the By-Laws.

Mr. Woolson then moved that the meeting approve the proposed amendments in the form in which they had been offered and order them submitted to letter ballot. The motion was discussed by G. K. Parsons who asked if the action would preclude the operation of the Nominating Committee newly created.

H. H. Vaughn wished to have the word "adopt" in C50 interpreted, and was asked to prepare such an interpretation with Robert I. Clegg, who offered his understanding of the meaning of the term. It was subsequently decided that the term would be interpreted in the by-laws.

L. P. Alford and Irving E. Moulthrop also spoke on the motion, and R. H. Libbey sounded a note of warning against the ill-considered adoption of standards by the Society. R. H. Fernald called attention to a typographical error in C45.

The Secretary presented reports of Standing and Special Committees.

The preliminary Report of the Committee on Pipe Threads was presented by title by the Secretary and it was moved that the Society receive and order printed the report.

The Report of the Sub-Committee on Railway Locomotive Boiler Code was presented by H. H. Vaughn and members interested in the discussion of the Report adjourned to the Council room immediately.

Junior and Student prizes were awarded by the President to E. D. Whalen (junior) for his paper, "Properties of Airplane Fabrics," to C. F. Leh (junior) and F. G. Hampton (student) for their paper, "An Experimental Investigation of Steel Belting," to W. E. Helmick (student) for his paper on "An Experimental Investigation of Steel Belting." F. G. Hampton was present and received his prize in person. Upon a question by L. P. Breckenridge he informed the meeting that he and his collaborator were connected with Leland Stanford University, California.

Ira H. Woolson was called upon to introduce the chairman of the Sections Conference, A. C. Booth. In his remarks Mr. Woolson explained that the Society had taken action to create new machinery for the operation of the Nominating Committee in the nomination of officers of the Society. Legal advice had been obtained so that nominations had been made by the Sections delegates in conference, their action to be legalized by the adoption of a by-law to read as follows:

The nomination of the members of the Nominating Committee for the year 1920 made by the delegates of the Local Sections at their session held December 2, 1919, shall, if not revoked, be a sufficient nomination of this committee by the said delegates within the intent and of these by-laws.

The Committee on Constitution and By-Laws voted to accept this opinion, provided proper action was taken subsequently with regard to the details of the new machinery.

A. C. Booth, Chairman of the Sections Conference then reported the following list of members recommended for approval by the meeting to constitute a Nominating Committee:

Howard P. Fairfield	.....Worcester, Mass.
George K. Parsons	.....New York, N. Y.
G. A. Wechsler	.....Washington, D. C.
Elliot H. Whitlock	.....Cleveland, Ohio
George W. Galbraith	.....Cincinnati, O.
Chester B. Lord	.....St. Louis, Mo.
Robert Sibley	.....San Francisco, Cal.

Alternates were recommended as follows:

William W. Varney	.....Baltimore, Md.
H. G. Tyler	.....New York, N. Y.
Samuel W. Stratton	.....Washington, D. C.
C. M. Spaulding	.....Erie, Pa.
H. M. Norris	.....Cincinnati, O.
J. A. Hunter	.....Boulder, Col.
E. O. Eastwood	.....Seattle, Wash.

It was voted that the recommendation be approved. Ira H. Woolson then moved that Council be recommended to adopt the temporary by-law necessary to legalize the action.

Memorial exercises in honor of Professor F. R. Hutton, including the presentation to the Society of a plaque, were held, Past-Presidents W. R. Warner and Ambrose Swasey, H. H. Suplee, Professor Hutton's sons, Mr. M. S. Hutton and Dr. Lefferts Hutton, being asked to take seats on the platform. The Secretary read the presentation address by William H. Wiley, acting Chairman of the Memorial Committee.

Past-President W. K. Warner spoke reminiscently of Professor Hutton and unveiled the plaque, which was accepted in the name of the Society by the President.

F. R. Low presented a memorial of William Kent, which was prepared by a committee of which he was chairman and distributed in pamphlet form at the meeting.

Major Fred J. Miller read a memorial to the members who had given their lives in the service and the following resolution was passed with a rising vote:

*Resolved:* That this Society hereby expresses its greatest appreciation of and pride in the services of its members who gave their lives that freedom might be preserved among the nations of the earth and that a copy of these resolutions be forwarded to the family of each of the members.

L. C. Marburg, Chairman of the Committee on Aims and Organization, presented the Report of the Committee to the Society. The discussion of the report was so lengthy that it was continued at an adjourned meeting in the afternoon and will be found in Section Two of this issue.

Morris L. Cooke presented an amendment to the Constitution, CG, which was received by the Secretary for presentation at the Spring Meeting as required by the Constitution.

### Appraisal and Valuation Session

The Committee on Meetings and Program has received requests from time to time for papers and discussion upon the subject of Appraisal and Valuation of Property, a question in which many engineers are interested and about the principles of which there is a wide diversity of opinion. It was therefore decided to hold a session on this subject at the Annual Meeting, and a Committee, of which President Cooley was chairman, was appointed to arrange the details.

It subsequently developed that the American Society of Refrigerating Engineers, whose Annual Meeting occurs simultaneously with that of The American Society of Mechanical Engineers, were proposing to hold a similar session, and a joint session of the two Societies was accordingly planned for Wednesday, December 3. Papers contributed by the Refrigerating Engineers were upon Ice-Plant Depreciation, by George E. Wells, president of that society, and upon Depreciation of Insulation, by J. E. Starr. The A.S.M.E. contributed a paper on Appraisal and Valuation Methods, by David H. Ray, an abstract of which appeared in MECHANICAL ENGINEERING for December. Supplementing this was a series of contributions, carefully developed by the Committee in charge, for a progressive discussion of certain fundamentals upon which a plan for valuation methods might be based. These papers were as follows: Fundamental Principles of Rational Valuation, by James R. Bibbins; Development of Project, by the late F. B. H. Paine; The Construction Period, by H. C. Anderson; Price Levels and Value, by Cecil Elmes; and Original Costs and Normal Values, by R. H. Nexsen.

There was very evident interest in the session, as it was largely attended and the discussion lasted until a late hour. In fact, the attention which the subject received and the evident approval of those present led to a motion recommending that a committee corresponding to the Boiler Code Committee of the Society be appointed to go into the subject of appraisal and valuation, making a study of it for several years if need be, trying, if possible, to bring order out of chaos in respect to the methods to be followed. This motion was carried.

Inasmuch, however, as no opportunity was afforded for the proper digesting and discussing of the several papers presented at this session, it has been further proposed that certain or all of the papers be distributed in advance of the St. Louis meeting to be held next spring, and that discussion upon them be solicited for that meeting. It is probable that this will be done and that a digest of the discussion given at the Annual Meeting will also be sent out. In view of the situation, therefore, no attempt has been made at this time to report the discussion on appraisal and valuation at the Annual Meeting. Should the matter be assigned to the St. Louis meeting, as proposed, a suitable review of the whole matter will undoubtedly then be published.

### Gas Power Session

The Gas Power Session was held on Wednesday afternoon, Dean Benjamin of Purdue University, presiding. The following papers were presented: The Hvid Engine and Its Relation to Fuel Problems, by E. B. Blakely; Combustion of Heavier Fuels in Constant-Volume Engines and in Engines of the Superinductive Type, by Leon Cammen; Kerosene as a Fuel for High Speed Engines, by L. F. Seaton; and Oil Pipe Lines, by S. A. Sulentic. The first two of these papers appeared in abstract form in the December number of MECHANICAL ENGINEERING on pages 918 and 941, respectively; the last two in the November issue on pages 881 and 883.

Mr. Blakely's paper drew forth considerable discussion in which the following points regarding the Hvid engine were brought out: The standard types are 1½, 3, 6, and 8 hp., but larger units such as 15, 20, 30 and 60 hp. per cylinder are also being made. One marine concern is putting out a 25-hp, 4-cylinder block design with an electric starter; another is building 2, 4, and 6-cylinder units.

The cheapest grades of oil may be used for the Hvid engine as long as they are clean, free from grit, and will flow readily. The author told how crankcase oil obtained from a garage, after being strained through a piece of cheesecloth, was used by one concern to operate two of these engines. Undoubtedly this procedure saved several thousand dollars. Two fuel cups are supplied with each engine and about a half-hour is required to change over from a light-oil engine to a heavy-oil engine.

Carbonization in the cup may be attributed to the following causes: the cup being too hot when heavy oil is used; a cup designed for kerosene being used for heavy oil, or leakage occurring between the cup and the atmosphere. Other than these, the author knows of no other causes of carbonization.

Several of these engines have been running on test to see how long they will stand up and how long it will be before there will be trouble with the Hvid principle. Three 8-hp. engines have been running between five and six months. One of them has been in operation, both day and night, for a little over five months, with one shutdown, the cause of which is unknown, which occurred over two months ago. Since that time this engine has been running continually.

H. Schreck<sup>1</sup> took exception to the author's statement that the Diesel engine cannot be built for smaller units than 100 hp. He pointed out that a German firm has made a practice of building Diesel engines down to 8.5 hp. and has shipped them by hundreds to South America and Russia. In reply, the author stated that no small Diesel engines had been made in this country, and moreover that from the standpoint of initial cost, a small Diesel engine, with its complicated air compressors, could not compete with the simply constructed Hvid engine.

L. F. Seaton's paper on Kerosene as a Fuel for High-Speed Engines was read by title only.

In presenting his paper on the use of heavier fuels in constant-volume engines, Mr. Cammen pointed out that the gas turbine today is in the same state as aviation was before the advent of the Wright Brothers; moreover, the Wright Brothers of the gas turbine have not yet appeared. The United States, he said, is the greatest automobile-producing country in the world; nevertheless, during the past three years, more has been done abroad in the development of the new types of the internal-combustion engine, particularly as regards the superinduction types. Unless American engineers consider the effect of mass production and look to the future more carefully, we are apt to lose out in the automobile field just as, very unfortunately, we lost out in the development of the American invention, the aeroplane.

In the author's absence the paper by S. A. Sulentic was read by title only. In view of the fact that oil pipe lines have been so highly developed in this country, and further, that many available data exist in the hands of the builders and operators of these lines, Professor Lucke<sup>2</sup> expressed the opinion that such data should

<sup>1</sup> Consulting Engineer, New York City. Mem. Am. Soc. M. E.

<sup>2</sup> Prof. of Mechanical Engineering, Columbia University, N. Y. City. Mem. Am. Soc. M. E.

be filed, either in the form of papers or discussions, and that they appear in the TRANSACTIONS of the Society. Professor Lucke also offered a resolution, which later was passed, that copies of Mr. Sulentic's paper be sent to engineers connected with pipeline and similar industries, with a request that they present written discussions verifying the conclusions arrived at, or substitute others for them, and that they add as many data as they can, in order that this valuable compilation become part of the TRANSACTIONS.

## Session on the Industrial Situation in Relation to Present Conditions

At the session devoted to the Industrial Situation in Relation to Present Conditions, held on the morning of Thursday, December 4, four papers were presented, which, by reason of the vital importance of the subjects discussed, drew an audience that filled every seat of the main floor of the auditorium. These papers were: The Causes of Industrial Unrest and the Remedy, by Frederick P. Fish, Chairman, National Industrial Conference Board; Wage Payment, by A. L. De Leeuw, Consulting Engineer; Systems for Mutual Control of Industry, by William L. Leiserson, formerly Chief, Division of Labor Administration, Working Conditions Service, U. S. Department of Labor; and What May We Expect of Profit Sharing in Industry? by Ralph E. Heilman, Dean, School of Commerce, Northwestern University, Chicago. Owing to the absence of the author, Dr. Leiserson's paper was read by Secretary Rice. The discussion of these papers and of a set of resolutions offered by the New York Section required a continuation of the session throughout the afternoon. President Cooley opened the morning meeting, later calling Vice-President Spencer Miller to the chair. Prof. D. S. Kimball presided at the afternoon session.

Discussion of the papers was opened by the Hon. George M. Barnes, M.P., representing the British Joint International Labor Conference and who also represented Great Britain at the Peace Conference at Versailles. Mr. Barnes, in the course of his remarks, said that the labor problem in its essence was not only that a man should get higher wages and more to eat and better clothes, but that he should take his place on terms of equality with all other classes of the community. Workmen were no longer illiterate and could hold their own in discussions on economic subjects. Employers on both sides of the Atlantic were now recognizing this fact and also that workmen had the right to organize and bargain for the disposal of their labor through agents. He did not think that profit sharing would appeal to the workmen unless it was applied to organizations of labor over wide areas on a national basis instead of to isolated establishments. Paternalism was well enough when shops were small and when every employer could know his men, but was no longer feasible in the present era of large-scale production where an establishment sometimes employed twenty to thirty thousand men. The best way to abolish the industrial unrest, in his opinion, would be to recognize that the workmen had equal rights with capital to organize on a large scale, and he believed that frankly recognizing this fact would contribute to increased production and to the benefit of all concerned. Mr. Barnes' remarks were greeted with hearty applause.

A. L. Siff submitted a written discussion in which he stated that strikes, lockouts and the like were as unnecessary today and as unjustifiable as any of the more serious breaches of civil and criminal law. We had built up a system of courts and legal procedure to adjudicate all civil and criminal disputes and we should adopt the same system to adjust labor questions. He outlined an elaborate plan for such adjustments which included a conference council in each company, as well as courts of appeals and various industrial zones for the country at large.

Harry Alexander<sup>2</sup> wrote describing a profit-sharing plan in which the men are rated in six classes, varying amounts being

deducted from their normal share of profits. These deductions form an efficiency fund, 70 per cent. of which is divided between the two first-grade men, 20 per cent. among the three second-grade men and 10 per cent. among the five third-grade men. The men are rated 60 points for loyalty, 15 each for ability and judgment and 10 for speed. The plan, he said, had been in successful operation for many years.

Lewis H. Nash<sup>3</sup> believed that the present labor unrest was due to the fact that so many people had come here from foreign countries who consider work more as a degradation than an honor. He looked with great suspicion on any scheme that tended to limit the rights of an individual to run his business for the mutual benefit of himself and his employees without intermeddling by outside forces, either governmental, labor-union or other, because he believed individualism to be the basis of democracy.

A. C. Jackson<sup>4</sup> said that one question which should be considered was whether or not labor unions should be compelled to incorporate, so that an agreement made between a responsible corporation and a labor organization would be between two responsible parties and not as now between a responsible party and one irresponsible before the law; and further, that if such incorporation was made compulsory, the present exemption of labor organizations from the Sherman Anti-Trust Law should be removed.

William S. Bowen<sup>5</sup> said that the struggle between capital and labor now centered about the question of control in industry. At present it was controlled by property. Looking upon wages as the interest that labor received from its capital, he thought it was possible to devise forms of control certificates, issuable to both labor and investors, that would amalgamate the interests of both, and gave a brief outline of the provisions of these proposed certificates.

Frederic L. Meron<sup>6</sup>, as his contribution to the discussion, presented particulars of a profit-sharing plan which he had recently published as part of a work on the Human Element in Organizations.

G. P. Hemstreet<sup>7</sup> said he had been urged many times to consider making partners of his workmen but felt that the union policy of limiting production hardly fitted a man to become a partner in a business. One thing that all could do was to see that their foremen became better acquainted with the men under them and treated them as human beings, for the foremen were the men who made or marred the reputation of a corporation with its employees.

Harrington Emerson<sup>8</sup>, discussing Mr. De Leeuw's paper, said that what was most needed today was some authority or some arbiter who would determine for the employer and employee what was just; who could settle the unit of measurement for both sides so that it would not be guesswork. He knew of an experiment where 12,000 men were employed, in which such an arbiter had succeeded after a few years in increasing the amount paid out as wages over a million dollars annually. This man and his assistants drew up thousands of work schedules which had to be passed upon by officers of the company and accepted by the men before they became operative.

Walter N. Polakov<sup>9</sup> said that so long as goods continued to be produced primarily for profit instead of for use, we could not hope to attain a maximum production. What could and must be done in this connection was to settle on the definite amounts of goods necessary for consumption and then see to it that those amounts were produced with a maximum economy and a minimum loss. Today industry was absolutely uncoordinated and unregulated. If we had a competent council capable of determining how much

and what goods were needed, as we had during the war, we might begin to see the light on other issues such as wage payment, organization of labor, etc., for these were capable of very simple solutions provided that those who were trying to settle them knew exactly what they were talking about and based their conclusions on facts, not on prejudices.

T. M. Ave-Lallemon, in an extended discussion of Mr. Fish's paper, challenged the statement that "one form of representation in industry is essential in order to make personal relationship possible under modern industrial conditions." He argued that representation in industry was a means of social control and not at all a means to the "resumption of personal relationship between employer and employed." What the workers meant definitely was a share in the control of industry through representatives of their own choosing. Piece-work, premium and bonus systems of remuneration were objected to by workers because they had no control of the determination of the rates employed. There remained as a further step in development the "collective labor contract," under which the workers contributed to the compound labor required in the production of an article agree collectively to do their work at a certain contract price for the whole job. This form of contract involved the complete determinateness of the piece-work contract, the principles of collective bargaining and the possibilities of acceptance by the workers of the principles of scientific management. Only in this way, in his opinion, could be much-to-be-desired maximum of production and minimum of cost be obtained.

#### RESOLUTIONS PROPOSED BY THE NEW YORK SECTION ON THE SUBJECT OF INDUSTRIAL UNREST

At the morning session, just prior to adjournment, L. P. Alford, representing the New York Section of the Society, took the floor and stated that the New York Section, during the preceding three months, had held a series of meetings to discuss aspects of industrial unrest. Acting in accordance with the wish expressed at one of these meetings, a brief declaration had been prepared on the subject, which was presented, discussed and approved at a largely attended meeting held on the evening of November 26, 1919, the motion of approval carrying a request that it be presented to the Council for their consideration and action. The Council had duly considered the declaration and referred it back to the Executive Committee of the New York Section, with a request that it be brought before the Society at the Annual Meeting. Mr. Alford then read the resolution together with two further resolutions which had been drawn up. At the afternoon session, following the discussion of the papers which had been presented in the morning, action was taken on these resolutions, and after a short debate they were adopted in the form given below.

#### RESOLUTION NO. 1—DECLARATION OF PRINCIPLES

Social and industrial unrest result from the fact that human relations have not kept step with economic evolution.

Competent directive management of essential enterprises is the logical solution. Such management must be free from autocratic control, whether by capital or by labor.

Sharp social or industrial disputes are no longer private. Society is affected, therefore such cases must be subject to the decision of authorities based upon intrinsic not arbitrary law.

Industry and public utilities must serve the people. There is no room for special privileges of capital or of labor. Strikes, irregular employment, or arbitrary acts of ownership or of management are harmful, not alone to the immediate parties but to society as a whole.

Productivity and public service are absolutely essential.

On account of the peculiarly intimate familiarity of engineers with industrial problems our responsibility is great.

Therefore, we, engineers and members of The American Society of Mechanical Engineers, declare that the following essentials are established by facts and experience, urge all of our members to uphold them, and invite other engineers to coöperate with us in having them unanimously recognized, viz.:

Every important enterprise must adopt competent productive management, unbiased by special privilege of capital or of labor, and disputes must be submitted to authorities based upon intrinsic law.

Credit capital represents the productive ability of the com-

munity and should be administered with the sole view to the economy of productive power, that is, it should be granted only to those who are able to render valuable service.

#### RESOLUTION NO. 2

Moved, That a Committee on Agencies of Productivity be established with sub-groupings to study among others these major agencies:

- 1—Invested savings
- 2—Credit capital
- 3—Organized labor
- 4—Unorganized labor
- 5—Employers
- 6—Managers
- 7—Society as a whole
- 8—Economic and productive intelligence service.

#### RESOLUTION NO. 3

WHEREAS, The vital necessity of immediate constructive action in the field of industrial relations is beyond dispute; and

WHEREAS, Industrial "Society at Large" obviously stands in need of some organ or agency of continuous productive initiative; and

WHEREAS, A declaration of principles upon which to base constructive action has today been approved by the Society in Convention assembled; be it

Resolved, That we, members of The American Society of Mechanical Engineers, undertake to formulate a practical program for industrial relations betterment; and further.

That this Society undertake to formulate a practical plan of organization to assist in determining what immediate steps can be taken to put industrial relations on a better footing and coordinate and make effective the splendid work now being done by various agencies; and further.

That the Council of the Society be requested to appoint a committee of five members of The American Society of Mechanical Engineers to study and to make effective this program.

### Machine Design Session

With the exception of one paper, the Machine Design Session, held in the Auditorium on Thursday, was devoted to a discussion of various types of rotating machinery. Dean Cooley presided and the following papers were presented in the order named: Reliability of Materials and Mechanism of Fractures, by Charles de Freminville, Hon. Mem. Am. Soc. M. E.; Tests on Dredging Pumps Used in Inner-Harbor Navigation Canal, New Orleans, by W. J. White; A Perfected High-Pressure Rotary Compressor, by C. B. Lord; Turbo-Compressor Calculations, by A. H. Blaisdell, and A New Type of Hydraulic-Turbine Runner, by Forrest Nagler. The papers by Messrs. Lord and Nagler will be found in abstract form in the November and December issues of MECHANICAL ENGINEERING; those by M. Charles de Freminville and A. H. Blaisdell will appear at some future date.

Mr. White's paper, which was presented by Prof. W. B. Gregory, was illustrated by numerous lantern slides and many of the views showing striking features of the work of constructing the New Orleans Industrial Canal are reproduced in connection with the abstract, which appears elsewhere in this issue.

It is of interest to recall in this connection that a similar problem was encountered during the construction of the Panama Canal and this fact was alluded to by H. Cadwallader, Jr., in the discussion. Mr. Cadwallader told of the difficulties of that work and how changes in dredging equipment increased the amount of material removed from 110,000 yd. per month to 225,000 yd.

During the discussion which followed Mr. Lord's paper, which consisted chiefly of a series of questions put to the author, it was brought out that the high-pressure rotary compressor he described will not be manufactured on a commercial basis because the principle involved is applicable alike to vacuum pumps, fluid pumps and air pumps, and it is thus obviously impracticable to manufacture the compressor in all its various forms. An organization has accordingly been formed for the purpose only of licensing other concerns to manufacture the particular type of compressor they require. For example, if a certain company requires a compressor for Diesel engines this new organization will supply them with drawings, act in a consulting capacity and give them a license to manufacture in their own shops the particular type of compressor they require.

In response to an inquiry Mr. Lord stated that the compressor

<sup>1</sup> Efficiency Engineer, Philadelphia, Pa. Mem. Am. Soc. M. E.

had shown a mechanical efficiency of 86 per cent and a volumetric efficiency of 92.7 per cent, but as to its adaptability to various types of work, such as the pumping of Mexican fuel oils or the compressing of casing-head oil, Mr. Lord was unable to give any definite data.

Turbo-Compressor Calculations, by A. H. Blaisdell, was presented, but by title only. The paper contains a discussion of the features which differentiate the turbo-compressor from the multi-stage centrifugal pump.

The final paper of the session was presented by its author, Forrest Nagler, of Milwaukee, Wis. The type of runner described in the paper is a decided step forward in the development of the hydraulic turbine and it is of interest in this connection to quote from the remarks of Clemens Herschel, a hydraulic engineer who was intimately connected with the early development of the turbine.

"The Francis wheel, so-called, is a misnomer," said Mr. Herschel. "He never invented anything of the sort that is now called the 'Francis wheel.' Of course, I knew him personally, and used to work with him. The so-called 'Francis wheel' was invented by a man by the name of George F. Swain. Of course improvements were made and in those days most of the development was done by what were called cut-and-dry methods. They would make a model and try it. If it did not work they would plug it or shave it down a little, and finally get it to suit."

## Discussion at Power Machinery Session

The discussion, of which a summary is here given, took place at the Power Machinery Session at the Annual Meeting and applies to the four papers which were read at the session: Emergency Fleet Corporation Water-Tube Boiler for Wood Ships, by F. W. Dean of the Emergency Fleet Corporation and Henry Kreisinger, engineer, U. S. Bureau of Mines; Flow of Water Through Condenser Tubes, by William L. De Baufre and Milton C. Stuart, of the U. S. Naval Experiment Station; Air Pumps for Condensing Equipment, by Frank R. Wheeler, of the C. H. Wheeler Mfg. Co., and The Thermal Conductivity of Insulating and Other Materials, by T. S. Taylor, non-member, of the Westinghouse Research Laboratory. Because of lack of room it has been impossible to give the discussion in complete form, but it is believed that what is presented here correctly records the most essential points that were brought out.

### EMERGENCY FLEET CORPORATION WATER-TUBE BOILER FOR WOOD SHIPS

In opening the discussion, Joseph J. Nelis<sup>1</sup> emphasized the radical departure for the merchant marine, accustomed to the Scotch marine boiler, in the introduction of the water-tube boiler on merchant ships. The chief differences between this boiler and the standard in use in the United States Navy existed in closer tube spacing, larger grate area and the fact that there was no superheater. The boilers were designed with large grate areas to accommodate the use of Pacific Coast coals and natural draft, although all ships were equipped with fans. The tendency in the merchant marine, he said, was toward higher pressures, superheat and the use of turbines.

T. A. Marsh<sup>2</sup> wrote that the results of the experimental work by Mr. Kreisinger both as regards baffling and air supply over the fuel bed correspond with much that has been done in commercial practice by boiler and stoker companies during the past few years.

In the development of improved heat absorbers additional passes have been given to the gases in some of the standard boiler designs. Some of the first designs lacked proper areas, did not make due allowance for soot removal, and were difficult to maintain, but recent designs have made provision for overcoming these difficulties.

In changing a boiler from a 3-pass to a 4-pass baffling, one must always consider the additional draft loss due to high resistance to the gases and the reduction in draft due to lower exit temperatures. It is necessary if some desired rating is required from the boiler, to insure that the draft after changing the baffles will be sufficient to assure adequate fuel consumption, otherwise in the effort to improve efficiency the capacity will be reduced.

Referring to air admission over the grates, there is no question but that the author is correct regarding the inability to force sufficient air through the fuel bed. Auxiliary air supplies have been introduced through bridgewalls, side walls, through arches, at the front of the furnace and in fact at almost every section of the furnace. This has proven of advantage in many instances, particularly with furnaces of limited capacity for combustion of the gases.

Mr. Marsh had seen several instances of increased efficiency due to the introduction of auxiliary air and was thoroughly in accord with the idea of installing systems for admitting air above the fuel bed provided they are installed and operated under the supervision of competent combustion engineers. There are many more installations suffering from a large excess of air than from a deficiency, and it is with great caution that we should advocate admitting air other than under the fuel bed.

Larger furnaces or stoker firing may afford a better solution to the problem. Each furnace requires its own specific investigation.

In a written discussion, Albert A. Cary<sup>3</sup> drew attention to the circulation within the boiler. Three hundred and eighty-eight 3-in. tubes generating steam, he said, had for their outlet to the steam drum 21 three-inch tubes. This disparity of area was not thus wholly expressed, but the relative volumes of water and steam must also be considered. By applying the usual formula for calculating the flow of steam through pipes, it could be shown theoretically that the twenty-one 3-in. tubes delivering steam from the rear header to the cross-drum of this boiler were not only ample in number and size, but that the steam was flowing at an absurdly low velocity. But it would be found that the difference in pressure between the rear header and the front cross-drum actuating the flow of steam was very small. Steam merely flows in these tubes as rapidly as steam is being taken from the boiler, and the pressure in the steam drum never falls very much below the pressure in the rear header.

During the course of his professional experience, he said, he had been called upon to perform investigations which led him to experiments to determine the true velocity of circulation within a water-tube boiler. A light-running propeller wheel mounted in a thin disk of metal was placed in the tube in such a manner as not to interfere with the circulation of the water. The number of revolutions of the propeller was recorded by an electric chronograph placed outside the boiler and varied with the velocity of circulation. While the experiments were unsuccessful so far as determining the actual velocities was concerned, he was able to discover that the direction of circulation was not as he had supposed. The upward circulation from rear to front headers was very rapid in the several lower layers of tubes. Above the vertical center of the bank of tubes there was little or no velocity of flow; while near the top there was a reversed circulation, from the front, back to the rear headers. This showed that the outlets from the top of the headers to the steam drum could not deliver the steam from the tubes as rapidly as it was generated, resulting in reversed circulation. With the tubes thus largely filled with steam their value as heating surface became diminished.

He discovered subsequently that these observations had also been made by M. Brull, the French engineer, with boilers of the Babcock and Wilcox type. In England he had seen the efficiency of boilers greatly increased by the use of steam-extraction tubes which delivered the steam directly to the steam drum as soon as it was generated.

L. P. Breckenridge<sup>4</sup> congratulated the Society upon having pre-

<sup>1</sup> Asst. Engr., Emergency Fleet Corporation, 140 North Broad St., Philadelphia, Pa.

<sup>2</sup> Chief Engineer, Green Engineering Co., East Chicago, Ind. Mem.Am. Soc.M.E.

<sup>3</sup> 195 Liberty St., New York, N. Y.

<sup>4</sup> Professor of Mechanical Engineering, Sheffield Scientific School, Yale University, New Haven, Conn.

sented to it a paper by men so well qualified to do so as Messrs. Dean and Kreisinger, and pointed out that the complete combustion of fuel depended upon three things: the proper amount of air, mixed thoroughly with the fuel at the proper temperature.

R. Sanford Riley<sup>1</sup> thought that the water-tube boiler had made an effective entrance into merchant marine engineering practice, and that, due to the impossibility of obtaining skilled firemen at sea, the automatic stoker would soon come into use on ships.

John Van Brunt<sup>2</sup> said that underfed stokers had been used on ships and that there was no mechanical reason why they should not come into universal use.

In the closure of the paper, Henry Kreisinger said that the Bureau of Mines experiments had showed that the circulation in boilers was as Mr. Cary had pointed out, very slight in the middle section of tubes and in opposite directions in the sets of tubes above and below. He did not imagine that the reversed circulation in the tubes would cause steam to remain in them for very long. He announced that the investigations published in the present paper would be completely reported in a publication of the Bureau of Mines.

#### FLOW OF WATER THROUGH CONDENSER TUBES

The discussion on this paper, opened by Joseph J. Nelis, centered around the packing of condenser tubes in marine condensers. William de Baurfe said that the present marine practice with the Navy was the rolled joint with bent tubes to take up expansion and contraction strains. Edwin B. Ricketts<sup>3</sup> thought that the corset-lace packing of standard stationary condenser practice should prove equally as serviceable at sea as on land and John F. Grace<sup>4</sup> said that he had inspected condensers on a recent destroyer where the corset-lace packing had been used.

Philip E. Reynolds<sup>5</sup> and G. L. Kothny<sup>6</sup> asked about the friction losses at the entrance of the tubes, and R. J. S. Pigott<sup>7</sup> wanted to know if any condenser manufacturer had attempted to eliminate much of this entrance and exit friction by chamfering the ferrules. August H. Krues<sup>8</sup> said that he had always specified chamfered ferrules, and John F. Grace drew on the blackboard a diagram of the chamfered ferrule made by his company.

In closing, Professor de Baurfe said that the experiments showed a loss of about 3 ft. of tube due to the entrance and exit friction, and that further experiments should be performed to see if it would be possible to reduce this to, say, 1 ft. He had no data on the effect of bent tubes.

#### AIR PUMPS FOR CONDENSING EQUIPMENT

By far the liveliest discussion of the Power Machinery Session was that on the paper by Frank R. Wheeler on Air Pumps for Condensing Equipment. After presenting the important features of his paper orally, Mr. Wheeler was followed by George J. Foran,<sup>9</sup> who read a lengthy discussion of the paper. Mr. Foran thought that the paper conveyed the impression that recent progress in the maintenance of high vacua was due to the introduction of the steam-ejector type of air pump, and gave evidence to show that such high vacua had been obtained by the rotative dry-vacuum pump in use for many years in commercial operation. He contended that every manufacturer of condensing equipment made ejector-type air pumps, and offered them for situations where he considered them advisable. His company had had no call for such pumps from the more important power plants.

He called attention of the members to a paper read before the National Edison Companies, in 1913, in which the hydraulic and rotative dry-vacuum pumps were compared. The power required by the hydraulic pump was several times that required by the rotative dry-vacuum pump, not 40 per cent as stated in the paper.

He submitted the performance curve of the Muller hydraulic pump (Fig. 1) with the statement that the pump had no small passages or sharp edges as stated by the author. He questioned accuracy of the figures given, and pointed out that the author had assumed an increased temperature corresponding to adiabatic compression which was true only for the steam ejector. The compression for dry air in the hydraulic vacuum pump was known to be isothermal. He then showed the effect of the actual conditions where the air was not dry, and that the hydraulic vacuum pump required less power than the ejector pump.

Mr. Foran criticized the author's statement regarding the mixture of air and water vapor, and said that the process should be

FIG. 1 PERFORMANCE CURVE OF MULLER HYDRAULIC PUMP

clearly indicated by which the method of determining the relative volumes was deduced, and he thought that with Fig. 5 (MECHANICAL ENGINEERING, December, p. 930) should have been shown also the curve showing volumes of 1 lb. of air at different pressures and temperatures of saturation. This curve, he contended, was applicable to the determination of volumes. He pointed out the discrepancy in figuring the volumes as had been done by the author.

With regard to Fig. 4, he pointed out that for the smaller capacities much less air allowance was shown than previously had been used, both in this country and abroad. On the other hand, the curve showed a much greater allowance than was required under actual conditions for the larger capacities.

Commenting on the statement that "the ratio of compression in the two stages (in the two-stage ejector pump) should be kept as nearly equal as possible," Mr. Foran pointed out that patents had been applied for such pumps under claims that:

- Compression in first stage was greater than in second.
- Compression in second stage was greater than in first.
- Compressions in both stages were equal.

Philip E. Reynolds read a discussion in which he agreed with the conclusion of the author that the ejector type of air pump was the air pump par excellence. The fault of reciprocating pumps lay in the fact that the volumetric efficiency fell off very rapidly when high vacua were approached, that it was difficult to maintain high volumetric efficiency and to lubricate the pump.

He thought that the hydraulic air pump failed to meet the requirements in that it could handle only small quantities of air and was somewhat unstable at low vacua. The power required to obtain high vacua was very high. The openings were small

and liable to become clogged; it required expensive equipment and the maintenance was high.

He said that the vacuum obtainable in a given condenser depended on the design and size of the condenser, the amount and temperature of the circulating water and the effectiveness of the air pump, and gave the basis for these statements. From an engineering standpoint, and with a given condensing equipment, the air pump which would remove the greatest volume of saturated air from the condenser would produce the best vacuum. However, there must be a compromise involving steam consumption, and the benefits derived from the increase in vacuum which might be obtained by increasing the volume of saturated air removed. It could readily be shown by simple mathematics, applying Dalton's law, that excessive volumes of saturated air might be removed from a condenser with only a negligible increase in vacuum. Just what volume it was best to specify to be removed depended on the design of the condenser, the temperature of the saturated air, steam consumption, benefits derived from increased vacuum, etc.

He said that the author's method of selecting the size of a pump was very simple, but was based upon the temperature of the saturated air leaving the condenser for determining which he gave no method excepting to state that it was assumed to be an average between the circulating inlet and outlet temperatures. This assumption could hardly be considered as accurate. It was not possible, he said, to obtain the temperature of saturated air by the usual mercurial thermometer and he had been led to regard the inconsistent readings obtained in attempting to determine this temperature as worthless as the basis of mathematical calculations.

He pointed out that the Croll-Reynolds evacuator, shown in Fig. 10 of the complete paper, used two second-stage ejectors, each having different capacities. This gave the pump three capacities, a combination of the first with each of the second stages separately and the first with the two second stages combined for maximum capacity, thus obviating the use of two pumps.

The conclusion of the reading of the written discussions was a signal for advocates of the rotative dry-vacuum pump, the hydraulic vacuum pump and the ejector pump to vie with one another in debate, every speaker suffering the common fate of being misunderstood and of misinterpreting the meaning of his opponent's remarks.

Those taking part in the discussion were D. W. R. Morgan,<sup>1</sup> who contested that the openings of the hydraulic type of pump were not small, that the condenser manufacturer was interested in selling to the purchaser the type of pump best suited to his needs and that the capacity of the air ejector depended upon the vacuum; Paul A. Banef,<sup>2</sup> who argued that the methods of computing the size of the air pump from Fig. 5 and from Dalton's law would give different results; John F. Grace, who suggested that the temperature in the dry air pipe could be found by means of a bare thermometer passed through a cork, and that air leakage with a view to its reduction was the great question to be investigated by the engineer; William G. Starkweather,<sup>3</sup> who thought that the question of air pumps came down to one of simplicity and reliability, and whether due to design or other factors, there was a demand for ejector pumps; G. L. Kothny, who devoted himself to a refutation of Mr. Foran's and Mr. Morgan's criticisms; and John H. Lawrence,<sup>4</sup> who also pointed out that Fig. 4 was misleading.

An amplification of the remarks at this session will appear in TRANSACTIONS.

In his oral closure, Frank R. Wheeler answered as many of the criticisms as the circumstances would permit. He called Mr. Foran's attention to the paragraph in the paper in which he stated that the Muller hydraulic pump was a distinct type to which the

remarks in a later paragraph did not apply. With reference to air leaks, he was under the impression that he had made it clear that this was a great defect. In different installations, conditions would vary, so that the curves given in the paper might or might not apply. In any case, they were the curves used in determining sizes of pumps furnished by his company, two pumps being furnished for each installation. In answer to an objection that had been raised to the ejector pump in that it would not perform properly under reduced steam pressure, Mr. Wheeler pointed out that the ejector pumps were furnished with pressure-reducing valves which supplied them with steam at 105 lb. pressure, the pressure for which they were designed to operate.

An abstract of the paper on Air Pumps for Condensing Equipment will be found in the December, 1919, issue of MECHANICAL ENGINEERING, the figure numbers in the foregoing discussion referring to that abstract.

Owing to the fact that T. S. Taylor, author of the paper entitled The Thermal Conductivity of Insulating and Other Materials, was unable to be present, the paper was presented by title only. There being no one to discuss the paper, the meeting was adjourned.

## Textile Session

At the Textile Session, called to order by C. T. Plunkett, chairman of the sub-committee on Textiles, on Thursday afternoon, the following papers were presented: Teaching and Training Mill Employees, by Roy DeMitt; Steam Use in Textile Processes, by Geo. H. Perkins; Electric Power Supply to Southern Mills, by J. E. Serine; and Possibilities of Mechanical Handling of Materials in Textile Mills, by Kenneth Moeller. All of these papers with the exception of that by Mr. Perkins will later appear, in abstract form, in MECHANICAL ENGINEERING. Mr. Perkins' paper will be found on page 14 of this issue.

Mr. De Mitt<sup>1</sup> in presenting his paper on Teaching and Training Mill Employees, told of the methods employed in the southern states to educate mill operatives. Many of these mills run ten hours a day, and under the Federal Child Labor Act it is not permissible to work those under sixteen years of age over eight hours a day. After careful investigation it was decided to split the day into two five-hour shifts, and to compel the child operative to attend school for the remainder of the eight hours. This system, together with compulsory school attendance, has been extensively adopted throughout the South.

Four types of vocational school are employed: The vestibule school, in which would-be operatives are trained for their particular work when entering a mill; the all-day school, which the operative attends on alternate days; the part-time school, which the operative attends during part of each working day; and the evening school, which is attended outside of working hours. Short courses are offered because it is impossible to get the operative to sign up for a great length of time, and it has also been found advisable to teach subjects which will be of immediate use to the student rather than those of a more theoretical nature which might be of some practical use in the future.

The Smith-Hughes Act, providing for industrial education as well as other types, carries with it an appropriation of \$7,000,000 per year. In the South the agricultural people get the bulk of this, although the state boards are usually in a position to render considerable financial assistance.

George H. Perkins presented his paper with the aid of lantern slides, and showed the useful results of a great deal of laborious research. Chas. T. Main<sup>2</sup> recalled the great dearth of information on the subject and emphasized the fact that it is very desirable to have such data for future reference.

Because of the absence of the author, J. E. Serine's paper was read by title only.

Kenneth Moeller's paper, illustrated by means of lantern slides, discussed different methods of transporting material from one part of a mill to another by means of conveyors. Among the

advantages of such systems are: that the trucking is done "on the ceiling" instead of on the floor, and that the mill requires about 20 per cent less operatives.

## Transportation Session

At this session, held on the morning of Friday, December 5, in the Auditorium, Prof. W. B. Gregory presiding, two papers were presented, namely: Scientific Development of the Steam Locomotive, by John T. Muhlfeld, and Motor-Transport Vehicles for the United States Army, by John Younger. Abstracts of these papers appeared in the November issue of MECHANICAL ENGINEERING.

### SCIENTIFIC DEVELOPMENT OF THE STEAM LOCOMOTIVE

Discussing this paper, F. J. Cole<sup>1</sup> wrote that much remained to be done in the way of designing boilers to safely and economically operate under pressure of 350 lb. and over. Hard riding, he said, did not always arise from improper counterbalancing, but might be due to worn driving-box bearings, etc. When more than four driving axles were used, flange wear should be taken into account and lateral-motion driving boxes or conjugated leading trucks employed. Attention should be given to details of domes and throttle valves so that water is not carried out into the steam pipes. The increasing cost of fuel seemed to warrant the use of many devices not considered economically desirable a few years ago.

Clement F. Street<sup>2</sup>, discussing rule-of-thumb methods in design, said that scientific methods were all right in their place, but when it came to locomotive boilers, the thing to do was, as the late M. N. Forney had said, to "make the boiler just as big as you can." As to stoker-fired engines burning more coal than those hand-fired, that was the very purpose for installing the stoker—it was not intended as a fuel saver.

George L. Fowler<sup>3</sup> said that in regard to the disadvantage of using trucks, experience had shown that a symmetrical-wheelbase engine such as the Mikado type was much harder on the rails than a Consolidation engine, which has an unsymmetrical wheelbase and no trailing wheels on the back. He was unable to say what was to be gained in the way of evaporation by rapid circulation in a locomotive boiler, but it was an excellent thing as far as internal stresses due to expansion were concerned.

H. B. Oatley<sup>4</sup> wrote expressing his belief that a locomotive-boiler pressure of 500 lb. would be safely and economically used in the near future. Further, that the present method of transmitting power would be superseded by an improved type of construction that would result in the elimination of considerable unbalanced reciprocating and rotating weight and consequently in less rapid deterioration of rail, rail bed and driving mechanisms. Condensing operation would also be adopted.

Otto S. Beyer, Jr.,<sup>5</sup> said that in any discussion of the economy of electrified roads the possibilities of the super-power plant, located in the coal district itself and doing away with fuel haulage, should be considered. With rising labor costs it seemed to him that a premium would be placed more and more on speed in railway operation, which in turn would mean faster locomotives. The time element would also have to be taken into consideration in the matter of train loading. It was not a question of what a locomotive could haul up the maximum grade at the slowest possible speed.

Edwin B. Katté<sup>6</sup>, referring to the author's remarks on the electric locomotive, said that the fact that nearly every large railroad in the country is now operating a part of its system

electrically would indicate that the capital cost is not prohibitive. As to interchangeability, steam locomotives did not habitually leave the divisions to which they were assigned, nor would electric locomotives. There was hardly an electrification nowadays but what had the advantage of two or three or possibly six or eight power stations feeding into its own transmission system by various routes. In regard to congestion of road, it was quite generally accepted that a yard or terminal or line would have its capacity increased 25 per cent or more by electrification. As to operating costs, it was not difficult to arrive at the cost of electric operation; the difficulty was to obtain the comparable cost of superseded steam operation. As to tie-ups, it had been the experience of most steam roads that during snow storms and blizzards the electrified divisions operated more nearly 100 per cent than the steam divisions.

George Gibbs<sup>7</sup> wrote that electric traction was too big a subject to be disposed of in a few paragraphs. The author was mistaken in his belief that expected results had not been quite generally attained. More money had been made for the stockholders by reducing operating expenses, or by producing new business either by more attractive or more reliable service, or by an increase of capacity of the railways' facilities. He thought it entirely creditable to engineers that they had been able in the short period of, say, ten years' time, to develop electric locomotives which are reliable in service, have a moderate upkeep cost and which exceed in hauling capacity the most powerful steam locomotives.

Mr. Muhlfeld, in closing, said that in the boiler being designed for higher pressures the largest diameter of the shell, which was made of 1 1/4-in. plates, was 68 in. This was about as large a boiler as could be handled at present by locomotive builders. Mr. Oatley had referred to 500 lb. pressure. What had limited him in his argument in the paper to 350 lb. was the cylinder temperature, not boiler troubles; and tests made during the past three years had shown that a higher temperature than 750 deg. Fahr. would be one that would destroy the cylinders, packing and bushings.

In the matter of burning coal, to which Mr. Street had referred, he would say that during the past five years he had made numerous tests of the cinders taken from the back of a stoker-fired locomotive and from accumulations in small boxes placed on top of a freight train, and had found that in nearly every case they were unconsumed particles of fuel. The coal was being put through the boiler but was not being burned.

In regard to questions propounded by Messrs. James H. S. Bates and Wm. H. Wood, he would say in reply to the former that the steam turbine had not as yet been adapted to the locomotive, and to the latter that fireboxes with flexible stays were being eliminated.

### MOTOR-TRANSPORT VEHICLES FOR THE UNITED STATES ARMY

The discussion of this paper was opened by Arthur J. Slade,<sup>8</sup> who said that the most intelligent opinion of the A. E. F. would undoubtedly disagree with the author's statement regarding operation of trucks off the roads. Any vehicle running on wheels required a supporting foundation, even caterpillar tractors, and in France before vehicles could keep pace with advancing troops it was always necessary to repair the worst spots in the roads. The matter of personnel was vital as with the most highly refined types of equipment, military motor transport in the mass could not function properly without systematic organization. He believed that the solution of the intricate questions involved could best be found by a commission of really qualified experts who had been associated with the M. T. C. activities in the A. E. F. and who in cooperation with a board of army officers with similar experience could work out a sound constructive program that would justify the support of both the regular army and the general public.

<sup>4</sup> Chief Engineer, Locomotive Superheater Co., New York. Mem. Am. Soc. M. E.

<sup>5</sup> Captain U. S. A., Washington, D. C. Jun. Mem. Am. Soc. M. E.

<sup>6</sup> Chief Engineer, Electric Traction, U. S. R. R. Administration, New York. Mem. Am. Soc. M. E.

<sup>7</sup> Consulting Engineer, Gibbs & Hill, New York. Mem. Am. Soc. M. E.

<sup>8</sup> Lieutenant-Colonel, Aviation Section, Unattached, A. E. F. Mem. Am. Soc. M. E.

F. H. Pope<sup>1</sup> said that doubtless more rugged truck construction was necessary in military than in commercial vehicles, but army experience was apt to be misleading on this point as they had found the great cause for vehicle breakdown to be poor operation. As to the advisability of the 3-ton type, he would say that this type was urgently recommended for our army in 1916 by officers who had had actual motor-transport experience. The 1½-ton truck had its special value over a heavier truck in being more rapid, entailing less loss of capacity in bulky loads and being the truck par excellence for personnel carrying, but it was open to the objection made by Mr. Younger. Special vehicles, he believed, should not be allowed where standard types would answer the purpose. Motor cars and trucks should be restricted by make or model, either in divisions or territorial districts. The 4-wheel-drive type had a very positive value, chiefly for artillery work, where their tractor properties could be utilized, and for cargo work over mountainous or difficult terrain. The caterpillar type, however, was the only one that was really serviceable in very difficult territory.

B. P. Miller<sup>2</sup> said that in the future the country would undoubtedly have a military policy, upon which would be based programs for any emergency that might arise, and he believed that motor-vehicle designers and engineers, manufacturers and military authorities should all have a part in perfecting such programs. The peace-time equipment of the army would probably be limited to that actually required for peace-time necessities but this equipment should be kept up to date by the yearly purchase and replacement of 20 per cent. of new equipment. He was of the opinion that we should not cling to the fetish of exclusive military design unless it could be shown to be capable of being produced more rapidly and economically than selected types of commercial design adapted to military requirements. Ford cars would be used in the future near the front lines and where the roads were bad, and light trucks would also be used to replace the animal-drawn vehicles of combat troops for cargo carrying. Four-wheel-drive trucks would always be required, not only for use with artillery and other hauling off the roads but also for cargo hauling. The use of trailers, in his judgment, should be limited to hauls that were obviously suitable and for mounting certain special equipment and bodies that were required to be moved infrequently.

William P. Kennedy<sup>3</sup> said he believed that standards must be effected by means of some compromise between military engineers and commercial engineers representing the most prominent manufacturers, who would discuss and lay down the principles that would be incorporated in the machines that were necessary to serve the army purposes. That is, the military organization could not expect to get all it would design or demand for its own interests and would have to accept a compromise between that and what the manufacturers considered it desirable to produce to remain in business and in such condition that they could produce quantities of trucks in a short time without great loss.

Alfred F. Masury<sup>4</sup> said that undoubtedly specially designed vehicles to meet the requirements of the army would be superior to any commercial vehicles, if for no other reason than on account of standard parts. The War Department, however, could not be expected to carry on hand in peace times a large stock of up-to-date war vehicles. It would therefore seem best to employ commercial vehicles so far as possible in the army and restrict the specially designed vehicles to those special uses for which truck and other special equipment was used. Commercial designers should be encouraged to incorporate in their designs features which might be of military use and which would also be of commercial use, such as provision for high gear ratios, etc.

G. R. Young<sup>5</sup> in an extended written discussion, said among other things that one reason for standardization that should be strongly emphasized was the importance of reducing as much

as possible the varieties of makes and types of vehicles for the army. Motor vehicles for army use should be capable of taking great overloads, withstanding rough handling and operating under bad road conditions. To make any program a success it would be necessary in peace times to have the army supplied with, say, 40,000 to 50,000 motor vehicles. Immediately on the outbreak of a war, 20,000 or more must be immediately obtainable. In four to six months, under the gruelling conditions of field service, the motor vehicles first sent out would begin to wear out and break down in large numbers and would have to be replaced. This would call for, say, 50,000 vehicles, with further large increments until the close of the war. The peace-time estimate under a five-year replacement scheme would call for 8000 new vehicles a year. The question was, would manufacturers be sufficiently interested in a share of this business to construct these standardized vehicles with tools and fixtures for which the Government assumed the expense of keeping up to date?

Mr. Younger, in his closure, said that those in charge at Washington had to face facts as they were and their policies had been developed from day to day instead of during the period preceding the war. The paper had touched on important points that should be considered in the policy that should govern us during the next few years. There must be no compromise decisions in the future. The question of personnel raised by Colonel Slade was one of exceedingly great importance. The automobile industry had been successively called upon to furnish personnel to care for the tremendous expansion in aircraft, fighting-tank, agricultural-tractor and submarine-chaser activities. The truck industry had to take what was left, which was one reason why many things appeared terrible overseas. While it was perfectly true that it had been found necessary to introduce new types of vehicles, if the war had lasted three years longer, which was expected at the last, he believed they would have been justified in their adoption.

As Mr. Kennedy had said, it was highly probable that a compromise would have to be effected, and one strong compromise suggested during the war was that vehicles of different makes be zoned. With a static battlefield as in France it would be easy to arrange these zones, but with a mobile battlefield as we had in Mexico other elements had to be considered. As to commercial-vehicle manufacturers supplying the vehicles in the future, if the army could dictate what kinds of guns and harness it was going to use, why should it not have the right to dictate, if it so desired, what type of motor vehicle it should use? One interesting thing in this connection was the question of roads. Millions of dollars were being spent on road construction and trucks would be designed more and more for use on highways, but it should be kept in mind that an army did not travel over good roads.

## Machine Shop Session

Four papers were read and discussed at the Machine Shop Session held Friday morning, December 5, under the auspices of the Sub-Committee on Machine Shop Practice. These papers were: Common Errors in Designing and Machining Bearings, by C. H. Bierbaum; Lubrication of Ball Bearings, by H. R. Trotter; Thread Forms for Worms and Hobs, by B. F. Waterman; and Electric Arc Welding, by H. L. Unland. The papers by Messrs. Bierbaum and Waterman will be found in the November issue of MECHANICAL ENGINEERING. Mr. Trotter's paper was published in the October issue.

Mr. Bierbaum's paper was a discussion of the disadvantages of tight-fitting bushings, the methods of finishing brasses to provide for expansion while running, and the methods of clamping bearings during tooling. The finishing of surfaces and the importance of using sharp tools with the proper rake was also considered.

In discussing Mr. Bierbaum's paper Frank L. Fairbanks<sup>6</sup> stated that while the principles set forth by Mr. Bierbaum were theoretically correct, it was nevertheless commercially impossible to obtain the conditions required by these principles; and even if it

were possible to maintain a full oil film between journal and bearing this would mean a projected area so large and a rubbing speed so low that it would be doubtful whether such machine could compete with one obtaining 750 to 1,000 lb. per sq. in. by letting the metal take some of the wear and tear.

Selby Haar<sup>1</sup> also discussed the paper and stated that because of the small clearance or radial air gap between stator and rotor, bearings for small alternating-current motors of the induction type must be manufactured with additional limitations to those mentioned by Mr. Bierbaum's paper. A looseness in the bearing of only a few mils, he explained, would cause a considerable percentage variation of air gap around the circumference of the rotor. He further remarked that inasmuch as motors are often shifted from one class of work to another it is necessary that motor bearings be more liberally designed than plain machine bearings.

C. H. Norton<sup>2</sup>, discussing the questions of oil filament, oil grooves, and heat, stated that he had come to the conclusion that all oil grooves were of no possible value. He referred to a pamphlet published by the Texas Oil Co., in which he said it was concluded from a series of experiments on heat and speed that the fact that a bearing is heated to about 210 deg. is probably proof that oil is in it and the surfaces are separated by fixed oil and they become cooler as the oil film becomes thinner.

Of the lubricating of ball bearings, the subject of Mr. Trotter's paper, but little is known, and this, according to the author, is chiefly due to the fact that there is no accepted method of determining the lubricating value of an oil or grease. In presenting his paper Mr. Trotter outlined a method which he has devised for this type of work. He also discussed the operating characteristics of a ball bearing and presented specifications for what he considered a satisfactory oil.

Henry Hess, in discussing the paper, suggested that the Research Committee of The American Society of Mechanical Engineers urge on Mr. Trotter the advisability of completing his investigations and that the Society aid by setting aside such funds as might be needed.

W. T. Murphy<sup>3</sup> said that 80 per cent of all trouble in bearings was caused by the presence in the lubricant of sand particles or other abrasives. Discussing the question of running anti-friction bearings without any lubricant, he observed that while such a procedure was theoretically correct, in practice the lubricant helped to overcome the slight friction that exists between the races of the bearings and the balls or rollers, and that there are cases where the use of grease or oil on such bearings is absolutely essential.

George N. Van Derhoef<sup>4</sup> challenged Mr. Trotter's conclusions as to the impossibility of there being an oil film between balls and races in a ball bearing. He observed that the research work so far conducted on oil films had been confined to bearings with much larger areas than there are in the case of balls traveling in the conventional raceway and also with surfaces with a different relative motion. He also pointed out that the difference in the coefficient of friction of lubricated and unlubricated ball bearings seemed rather to confirm the idea of an oil film existing in the case of the lubricated bearing.

H. R. Smith<sup>5</sup> claimed that the only practical method of gauging the lubrication qualities of an oil is by determining its viscosity value. In the case of a grease, the most important factors, he said, are the free acid—organic or mineral—or alkali, free fatty oil, solid matter, the character of the soap used and also the viscosity of the mineral oil employed in the manufacture of the grease.

Thread Forms for Worms and Hobs, by B. F. Waterman, was a discussion of both the theoretical and mechanical problems involved in the use of worm gearing. According to the author there has been a steady increase in the use of worm gearing and

accompanying it a corresponding increase in efficiency and durability.

In discussing Mr. Waterman's paper Henry J. Eberhardt<sup>6</sup> related an experience of the Newark Gear Cutting Machine Co. which led them to generate worm wheels having an angle of side of tooth of 14½ deg. In generating a worm wheel with a fly tool, according to the Noerstedt process, the fly tool having been made with straight sides and ground to 29 deg., included angle, the worm wheel thus generated would not run with a 29-deg. worm as it would not mesh. They, therefore, concluded that the only way to generate a worm wheel was to make a fly tool or thread on the hob of the same shape as the worm.

In the discussion of Mr. Unland's address on Electric Arc Welding, the question was brought up as to whether the Boiler Code Committee would accept and pass a boiler constructed and repaired by electric welding. In this connection Mr. Unland remarked that the question of repairing boilers had been previously discussed before The American Society of Mechanical Engineers, but as yet he did not know of any conclusions ever formulated in this respect by the Boiler Code Committee. He observed, however, that this type of repair is made and passed by all the shipping bureaus, Lloyds' and the American Bureau and others, on repairs to marine boilers, provided the company doing the work has the sanction of the underwriter. Mr. Unland stated that the majority of users are in favor of the direct current for electric welding, and that in this country the accepted practice is to use uncovered electrodes, while in England and on the continent of Europe the covered electrode is in favor.

## General Session

Four papers were presented at the General Session held on Friday morning, December 5. These were: Slow-Speed and Other Tests of Kingsbury Thrust Bearings, by H. A. S. Howarth; Octaval Notation and the Measurement of Binary Inch Fractions, by Alfred Watkins; Modern Electric-Furnace Practice as Related to Foundries in Particular, by W. E. Moore; and An Investigation of Strains in the Rolling of Metal, by Alfred Musso. Abstracts of all of these papers have appeared in MECHANICAL ENGINEERING, those by Messrs. Watkins and Moore in the November issue and those by Messrs. Howarth and Musso in the December.

Mr. Howarth's paper, illustrated by lantern slides, dealt with the application and tests of Kingsbury thrust bearings.

Mr. Watkins, whose paper was an argument for the adoption of a new method of measuring binary inch fractions, is a resident of England and his paper was presented by F. A. Halsey.<sup>7</sup> In the discussion following its presentation, Dean Benjamin brought out the fact that the question of measurement was not necessarily an academic one but rather a subject of broad interest to all engineers. Howard Richards, Jr., formerly associated with the University of China, advocated the metric system but Mr. Halsey maintained that the decimal system was hopelessly impossible as an instrument for reliable service; moreover, that the system advocated by Mr. Watkins was not a new one but merely a simplified method of using a system already existing.

The paper by W. E. Moore, on Modern Electric-Furnace Practice as Related to Foundries, was a discussion of the various features of the electric furnace which have made that type practically supreme in the field.

The paper by A. L. Musso, which was illustrated by lantern slides, dealt with one of the most important problems incidental to rolling-mill operation.

E. O. Goss, in a written discussion of Mr. Musso's paper, gave the results of a series of experiments made to determine the percentage elongation and side spread of cold-rolled brass, and while the results obtained differed materially from those given in the paper, Mr. Goss was of the opinion that this wide difference was not entirely due to the difference in material.

# President Cooley's Address

ANNUAL MEETING, 1919, OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

## A Survey of the Society's Organization, a Review of the Last Year's Accomplishments, and an Appeal to the Engineering Profession for National Organized Effort

IT is my pleasant duty on this occasion to tell you something of the doings of the Society during the year while I have been its President. And I thought you would also be interested to hear something about the way in which the Society does its work. For most of you, I feel certain, my story will be like the opening chapters of a new book. It will, in fact, be from the opening chapters of an old book, familiar to you in appearance, but, I dare say, one you have scarcely ever opened. I mean the Year Book of the Society.

First, however, let me tell you how much I have enjoyed the year and how much I appreciate the honor you conferred on me when you entrusted me with the responsibilities of administering the affairs of the Society. It is truly a great responsibility and growing greater with each year's growth of the Society—growth both in its membership and in its activities.

I remember well those first years, back in the early eighties, when our members were only a few hundred, and our activities confined principally to two meetings, one in the spring, the other in the winter. The contributions were chiefly the papers read at the two meetings and the discussion they provoked. Today there are over 12,000 members, 72 committees engaged in the work of the Society; 17 committees representing the Society on other organizations; 31 local sections; and 47 student branches. These are directed by a Council of 21 members assisted by the chairmen of the six Standing Committees of Administration and a paid Secretary with 76 assistants. Thus has the Society grown in the 39 years since it was organized in 1880.

The machinery of this great national society is really somewhat complicated. I assume that you are as ignorant of it as I was when I took my place at the throttle valve. Ah! happy thought! How easy to explain when the right analogy comes to one. As you know a throttle valve has two functions, one to start, the other to stop. At first I thought its most important function had to do with starting. But then I was guileless. I did not know my colleagues on the Council. "Throttle valve" is just the right word. How many times we would in our discussions have settled the affairs of the Nation had something gone wrong with the stopping function of that throttle valve; but as it happened the valve never got out of order; only individuals got "out of order."

Probably only a few of you know what the Council is. I need not hesitate to speak openly and with freedom, as knowing me as well as they do, it would not have surprised me had there been not a single member of the Council present here this evening. The fact that a number are present is evidence of the discipline to which they have been subjected; or it may be evidence of the possession of a conscience still active in pointing the way of duty. But let that pass. The Council is composed of the President, six Vice-Presidents, nine Managers, the Treasurer, and five Past-Presidents. They are a fairly quiet and orderly, not to say, modest lot of men—starting with the President at the top. But those past-presidents at the bottom! What shall I say of those past-presidents? And to think that I, too, shall so soon graduate and become one of them. But so runs the machinery of the Society. The last five presidents have a place on the Council. Thus each president has five years in which to make amends for any bad judgment he may have exercised during his one year of being first in responsibility. While these 22 men do all the voting, they do not do all the talking. There are the six chairmen of Standing Committees to be reckoned with on the floor in debate. That makes 28. But that is not all—far from it. There is also the Secretary. He is a spouting fountain—of ideas for advancing the interests of the Society, and the watchdog of its activities. No one of you knows how great is his responsibility to keep the

President functioning properly. The Treasurer of the Society is the only member of the Council who sits tight and says nothing.

Now that I have paid my respects to these gentlemen, my most immediate colleagues, let me say of them that it has been a rare privilege to be associated with such men in the great work of the Society. It is no mere honor as some have thought, to be a member of the Council. It means hard and conscientious work and vast quantities of it. If you could see these gentlemen sitting long hours around the Council Board, sometimes two full days at a time, you would realize how good servants of the Society they are. And let me tell you that were it more generally known how like horses these men have to work there would be fewer candidates, when the nominations for officers of the Society are made. The Council has held in all, during the past year, eleven meetings, one of them in Pittsburgh, two in Detroit and one in Indianapolis.

To my colleagues of the Executive Committee I would pay special tribute. They have been ever faithful in responding to calls for some emergency action. And many times I fear they have thereby been greatly inconvenienced. I was told I must choose nearby men in order to get them together, and even then I would rarely have a quorum. But I wanted to go ahead a bit in my selections for the Executive Committee and bethought me of a way to break down tradition. So I invited the Executive Committee to meet me at dinner. It worked like a charm. Not a man was absent. And at none of the many meetings we have held has there ever lacked a quorum. My heart goes out in gratitude to those loyal men who have so wholeheartedly helped the President over so many difficult places.

Next in our administration machinery come the six Standing Committees of Administration—Finance, Meetings and Program, Publication and Papers, Membership, Constitution and By-Laws, and Local Sections. I do not quite know how to tell you of my appreciation of the thirty men on these six committees. The amount of time and energy they give to the Society's work is enormous—appalling, I nearly said; but the word refers to the President, who must keep in touch with their several activities. The Society should know and appreciate the great care required and given so splendidly by the groups of five gentlemen composing each of our six standing committees of administration.

To aid in its work, the Meetings and Program Committee is assisted by six sub-committees, each charged with the responsibility of securing papers and preparing programs on particular subjects for sessions at the Annual and Spring Meetings of the Society. These sub-committees are really special committees in that they may be changed from time to time to meet the need of new subject-matter for presentation at the Society's meetings.

Next come the Standing Committees—House, Library, Public Relations, Research and Standardization. The Research Committee supervises all research activities, collaborates with kindred committees of other institutions and obtains results of researches conducted in other countries. It has at present seven sub-committees which are really special committees, each engaged in the investigation of some particular subject, such as the cutting action of machine tools, fuel oils, lubrication, fluid meters, worm gearing, bearing metals, and heat transmission. The latter acts jointly with a similar committee of the American Society of Refrigerating Engineers. The report of the Research Committee by its Chairman, Professor Arthur M. Greene, Jr., read at the Detroit meeting, merits wide attention. It deals with the subject comprehensively.

The Society has naturally a large number of special committees to deal with particular problems. These are formed as occasion

demands and discharged with the acceptance of their reports. Some of them are appointed annually and thus become standing committees for the year; such for example as the Committee on Junior and Student Prizes. Others are more in the nature of permanent standing committees, such as the Committee on Increase of Membership and on Student Branches. The latter is now called Committee on Relations with Colleges.

During the past year this Committee on Relations with Colleges has, under the direction of its Acting Chairman, Past-President Ira N. Hollis, made a comprehensive study of the Society's relations with educational institutions and of student and junior prizes. The report of this committee is very complete and well worth attention. It is the result of much hard work involving extended correspondence and study of other society organizations. The Council in accepting this report put itself on record as favoring prizes other than honorary membership, now accorded to persons of acknowledged professional eminence. Life membership, in addition to being acquired for a sum of money, could be awarded for the best contribution to mechanical engineering found in the papers for one year; Junior and Student Prizes, for papers of exceptional merit; a medal, for notable invention or some striking improvement in connection with the industries; honorable or special mention, for conspicuous contributions to engineering either of a practical nature or in literature; scholarships or fellowships, for exceptional attainments in college work; a medal or special mention, for exceptional achievement by Junior and Student members.

Rear-Admiral George W. Melville left a bequest of \$1000 to the Society for the award annually of a medal for the best thesis on mechanical engineering; and another gentleman has this year made a similar contribution. The Society allowed him \$1500 for expenses to France as the Society's official representative at the Franco-American Congress but he paid his own expenses and added of his own money \$1000, making his contribution \$2500. I refer to Past-President Charles T. Main.

The National Societies can well afford to further their relations with colleges. It is impossible to do too much toward helping to shape the ideals and ambitions of the youth of our country who are soon to take our places in the engineering world. The colleges would welcome the counsel of men in actual contact with the world's affairs. These engineers are giving little attention, or none at all, to the preliminary training of the young men they take on their staffs as assistants. They are, or should be, vitally interested; and they could if they would, be of great help in shaping the curricula of engineering colleges. Whatever the practicing engineer may think of his brother the professor-engineer—and his thoughts are, I fear, sometimes none too flattering—he must not confuse his brothers with clairvoyants. While college professors may be conceded to have wonderful imaginations, they stop short of being occult. The advice of the practicing engineer would be eagerly welcomed. If he thinks of us of the near-cloth as being diviners, let him at least show his hand to be read.

It cannot be said in these days that the college man works for money. His real compensation comes from the success of his students after they leave college and enter the practical world. Their training must still, and for several years, be in progress. Their teachers only are different. If we are to achieve greatest success in our profession of engineering, that is, have it stand at the forefront in world affairs, you to whom are turned over the young men from our colleges must do your part. When you realize what your part is, you will be both willing and anxious to help the college man in his part of the work. The four years in college should not be separated, as by a wall, from the years which follow. There should in those after years be the same inspiration to high ideals of life—those quite apart from money. Our country—the whole world—never needed high ideals more than it does today.

But let me get on with my description of the Society's machinery. The Boiler Code Committee with its five sub-committees still occupies a front seat in the Society's activities. The fact that our Boiler Code has been incorporated in the laws of thirteen states and seven municipalities, is a source of great satis-

faction and pride. It indicates a good work well done. The Boiler Code sub-committee on Railway Locomotive Boilers is very active. The railroads themselves through the Interstate Commerce Commission, have now sought the opportunity to cooperate in this work.

The Committee on Power Test Codes, reorganized in 1918, with 18 sub-committees, is a beehive of industry, and bids fair to rival the Boiler Code Committee for the Society's favor. Some of its sub-committees have already practically completed their work and submitted reports. Another year should get the important work of this committee well on toward completion.

Progress in various degrees is being made by other special committees. The Committees on Standardization of Feed Water Heaters, Shafting, Steel Roller Chams, have all reported progress. The Committee on Protection of Industrial Workers has recently completed jointly with the United States Bureau of Standards, an elevator code in which the Safety Committee of the National Association of Manufacturers participated. The special Screw Threads Committee and the Committee on Flanges and Pipe Fittings have been active. An international convention was recently called to meet in Paris to adopt a standard for pipe threads. This Society's official delegate is M. Laurence V. Benét, who resides in Paris; and to assist M. Benét technical advisors have been appointed from the Society's membership in various American industries engaged in the manufacture of pipe and fittings.

It will interest you to learn that standardization in general has recently taken a distinct step forward. The American Engineering Standards Committee is now, after being for several months the subject of active debate, an accomplished fact. While it is recognized that there are still several changes that could well be incorporated in its Constitution, it was considered better to get started and let experience determine the exact nature of those changes. The Committee starts off with representatives from the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Society for Testing Materials, and from the Government Departments of War, Navy and Commerce. The constitution provides for admitting to membership on the Committee, representatives from other societies and associations. This Committee does not create standards. That work is left to be done as now, by bodies especially interested in some particular standard. But the Committee gives its stamp of approval and serves as the medium through which standards are passed out to the world. One of the most useful functions of the American Engineering Standards Committee will be to cooperate with similar bodies in other countries in the formation of international standards; for instance, with the industries of Great Britain through the British Engineering Standards Association. When this Committee is functioning completely such matters as the coming meeting in Paris, of the Commission on an International Standard for Pipe Threads, would be handled by the American Engineering Standards Committee.

It will be remembered that last year at the Annual Meeting, President Main, after delivering his address, fled the country. I did not at first know the reason for his precipitate haste. I could scarcely imagine that it was because of the things he said in his address, although I now know that the President can say and do things amply justifying him in seeking safety. It was, however, an honorable mission that called him away. He went abroad as this Society's representative on a Committee of the four Founder Societies which was invited by the Société des Ingénieurs Civils and the Committee of the French Engineers' Congress, with the official approval of the French Minister of Armament, Public Works and Commerce, to study with French Engineers the rehabilitation of France after the war. Out of the service rendered by this Committee has come about the appointment of a Franco-American Committee in which this Society is represented by Charles T. Main and George W. Fuller.

Other exchanges of international courtesies that have afforded us satisfaction and pleasure during the year occurred in con-

nection with the Ottawa meeting of the Engineering Institute of Canada in February and the Detroit meeting of this Society in June. Past-President Hollis went to Ottawa as our special representative and Fraser S. Keith, Secretary of the Engineering Institute of Canada, came to Detroit as special representative of the Institute.

The James Watt Centenary celebration was held in England on September 16, 1919. In response to an invitation to participate, this Society sent as honorary Vice-Presidents Messrs. J. Wilfrid Harris, Harry F. L. Orcutt, R. Sanford Riley, and Wilson E. Symons.

This Society has had the pleasure of participating in extending courtesies to members of several delegations from foreign countries who have come to this country on various missions. Official delegations have come from France, Belgium and Switzerland. In fact, our distinguished guest of the evening, M. de Freminville, is a member of the French Engineering and Economic Mission which was invited to this country by the Chamber of Commerce of the United States. M. Schneider, the illustrious head of this Commission, was recently entertained by our sister society, the Mining and Metallurgical Society of America.

An interesting and important part of the mechanism of the Society's machine is the groups of members, known as Society Representatives, who represent this Society on other bodies. There are 17 of these groups, and the men who compose them are those who have been conspicuous in the Society's work, or have qualifications especially fitting them for the particular duties involved. These other bodies and committees are the American Association for the Advancement of Science, American Engineering Standards Committee, Classification of Technical Literature Committee, Cost of Electric Power Committee, Engineering Council, Engineering Foundation Board, International Committee on Screw Threads, International Standard for Pipe Threads, John Fritz Medal Board, Joseph A. Holmes Memorial Board, National Research Council, Naval Consulting Board of the United States, Standards for Graphic Presentation, United Engineering Society—its Board of Trustees and its Library Board, United States Bureau of Mines Advisory Committee, Western Society of Engineers, Washington Award Committee. The names themselves sufficiently describe the character of work involved making unnecessary any detailed description. The reorganization of the National Research Council on a peace basis includes its affiliation with similar bodies of other nations. The Chairman of our own Committee on Research has a place on the National Research Council.

The Regular Nominating Committee and the Tellers of Election must also be mentioned. The Nominating Committee was in the old days chosen by the President alone. But President Jacobus in 1917 inaugurated the policy, followed since, of inviting the Local Sections to make nominations from which the President could choose. But a new plan is to be followed in the future.

The Nominating Committee is to be elected by the voting membership, and tomorrow morning the Society will decide on the machinery. The proposal is to utilize the Local Sections organization for conducting the primary for nominations, every voting member being assigned to a local section for that purpose. The nominations are to be confirmed at the Local Sections Conference to be held at the Annual Meeting, after which the election will take place at the Annual Business Meeting. Thus will be insured, it is believed, a thoroughly democratic election.

In 1918 there were twenty-one Local Sections. Now there are thirty-one, an increase of ten during the year. Three of them are on the Pacific Coast. One local section in New England has five branches. This growth of Local Sections and extension of section responsibilities is one of the marked features of the Society's development. Like a wide spreading tree, the Society must have its roots and branches widespread if it is to grow and thrive. The roots must reach out into new earth and the branches out into sunshine. It is my firm belief that by increasing the importance of its sections the Society will add to its strength and vigor and render the greatest service to its membership.

As I see future development of the profession as a whole, it is important that the members of local sections of our own and other national societies should be also members of sectional and local engineering societies which embrace in their membership all engineers whether they be members of national societies or not; and which include those who work with engineers as members of their staffs, and who may not possess the qualifications for membership in the national societies. This, happily, is the plan being followed. Cleveland is a good example. There is now an arrangement, approved for trial by our Council, whereby our members who are also members of the Cleveland Engineering Society may have part of their dues to this Society remitted; that is, there is a division of dues. No doubt, considerable latitude will be permitted Local Sections in order to encourage them to work out plans for improving their own organizations. With increase in importance of Local Sections work, there will come the necessity of providing more permanent local headquarters. It has been suggested, and I believe wisely, that financial assistance should be given to local building projects through the aid of societies owning the Engineering Building here in New York, and by loans from surplus reserves. This subject may well have our earnest consideration.

One of the Sections Committee's recommendations is a Traveling Secretary whose duty it shall be to visit Local Sections and assist them in developing their plans. It is a good suggestion; but I would add to it. The President's duties have become very heavy. Notwithstanding that I have given one-quarter or one-third of my time to the duties of the office, I am sure that I have not done more than one-half of what the President should do. Among other things, it has been impossible to respond to the many cordial invitations to visit Local Sections. It has also been impossible to respond to many invitations from other national bodies to be present and participate in their deliberations and ceremonial functions. You will agree with me that these are proper and important duties of the President, and the dignity of the Society requires that they should be performed.

What I would add, therefore, is that the proposed traveling secretary be the President's representative. He could be styled "Assistant to the President." He should be a man of parts and worth a salary of at least \$5000 per year. With such assistance the President could perform many of his duties in whatever part of the country he might come from; that is, it would not be necessary for him to spend so much of his time at national headquarters.

This assistant could go to the President's home and stay a week or two at a time if necessary. He could represent the President at Local Section headquarters; or by lightening the burden of routine work, enable the President to go. Nor is this all. Many of the President's duties now necessarily fall on our Secretary, already overburdened with his own duties. The assistant to the President could relieve the Secretary of many of these, but not all of course. Certain very important duties could be performed by no one with more grace or with more complete regard for the proprieties and requirements, than by our Secretary.

In taking up the duties of President, it became evident to me after a time that pending the report of our Committee on Aims and Organization, it would be inexpedient to suggest or inaugurate any changes in the existing policies of the Society. It seemed rather a period during which the existing activities of the Society should be fostered and made as fruitful of results as possible. With this thought in mind, I undertook a study of committee work. As was to be expected with such a large number of committees, some of them were more active than others. Inactivity was not necessarily the fault of a committee. Some of the subcommittees were required to work only when called on. The work of other committees was temporarily suspended on account of the war. In a number of instances suspended committee work has been resumed.

One result of my investigation was to find frequently the same man serving on a number of committees, and only the older and more experienced members of the Society on many of the committees. While in some cases these conditions were warranted as

tending to give the best results, it seemed to me that for the good of the Society it was desirable to increase the number of individuals engaged on committee work by limiting one's membership to a few committees and by adding some of the younger men. In this way more general interest would be stimulated in the Society's work and the younger men would be trained for more responsibility later. Accordingly, Local Section officers were requested to canvass their membership for men willing to accept committee appointments. There is now on file a considerable list of men not only willing to serve but who have promised if appointed to attend to the work.

Another result of my investigation was to find the membership of many of the committees confined to within reaching distance of national headquarters here in New York. It is absolutely necessary, in a number of cases, to have at least a majority membership living nearby. The Executive Committee, the Finance, the House, the Library and the Membership Committees are examples. It is not advisable, in general, to have members of a committee come from widely separated parts of the country. It should be possible for them to get together without too great sacrifice of time consumed in travel, and without too great expense, which in most cases must be borne by the members personally.

It appeared that a solution of the difficulty might be found in choosing committee members with respect to localities. For instance, an automobile committee might be centered in Detroit and embrace Buffalo, Cleveland, Toledo, Jackson and Port Huron. A petroleum committee might be wholly from the Oklahoma or the California oil districts. A machine-tool committee might be wholly from the Ohio or the New England district, and similarly for committees on other subjects. A natural way with the increased importance of our local sections would be to choose the membership committee wherever practicable from the members of a particular local section. The local section itself could be held responsible for the work of the committee. The membership of such committees need not be confined to this Society. Indeed, it might be well, and in the interests of the Society as well as the work, to appoint some non-members. If they become greatly interested they might become members later. Committee work is of first importance in the Society, and should be well cared for. When it is of high order great credit comes to the members of the Committee and to the Society. It is the good work done by its members that enables the Society to occupy and hold its high place in the world. The honor of the Society is the honor of its members. The Society can give back only what its members put in both in kind and in quantity.

Of equal importance to that of Local Sections, if not greater, are the Society's publications. It is through them that the Society gives back to its members what they contribute in money and in work. Its Journal has been rechristened and is now called *MECHANICAL ENGINEERING*. It is the medium through which the membership at large can keep in touch with all Society activities, and become promptly informed on important engineering topics discussed at the annual and spring meetings and at the Sections' meetings throughout the country. During the year the Society has acquired the ownership of "Engineering Index" which it has greatly enlarged, and in which now appear regularly reviews or titles of articles from over eleven hundred periodicals properly classified and indexed. The Council has recently authorized an increase in the scope of the Journal so that it can be of still greater service to the membership.

With the desire to take part in and help solve, so far as it could properly, the industrial troubles of the country, the Council early in the year directed the appointment of a committee of seven to investigate and report on the feasibility of the Society actively participating in industrial questions. This committee made its report in February, advising that inasmuch as the constitution of the Society set forth as its object "to promote the Arts and Sciences connected with Engineering and Mechanical Construction," it was inexpedient to take any active part as a society in industrial matters; but that it was highly important that the members as individuals, or in their business capacity, should take such part as they could.

Believing that it would be helpful to the membership to receive the results of investigations of industrial conditions the Council in April authorized affiliation with the National Industrial Conference Board and appointed a representative on the Board. The propriety of the Society's holding such relations being later questioned the Council in October directed the appointment of a committee to report on the question of retaining our membership. This Committee, while unanimously commending the work of the National Industrial Conference Board was of the opinion that the Society should not hold membership in any other society or organization. The Council, therefore, withdrew from the National Industrial Conference Board at its November meeting held on December 1.

By far the most important work of the Society during the year has been that of its Committee on Aims and Organization. Inasmuch as the report of this Committee has been sent out to the membership and is to be discussed and disposed of at this annual meeting, I have not deemed it necessary, or even proper, to do more than call your attention to it and to urge you to take part in its consideration when presented. Suffice to say that certain recommendations of the committee have already had the attention of the council since they were favorably considered by the Society at its spring meeting in Detroit. I refer particularly to the development of Local Sections, the encouragement of Professional sections and the enlargement of the scope of the Society's journal, *MECHANICAL ENGINEERING*. We are all most appreciative of the work of this Committee. Theirs was a hard task, and while they would have welcomed an opportunity to carry their work further and perfect it, the Council thought that the Society would do well if it agreed upon and adopted even a few of the large number of recommendations made.

A most important part of the work of our Committee on Aims and Organization was its cooperation with similar committees of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, and the American Institute of Electrical Engineers. A joint committee of these four Founder Societies has held several meetings to consider and agree upon certain fundamental things as the basis for closer cooperation in the future. Without in any way sacrificing their identity and purpose, and leaving the chief aim of each to be pursued independently, it has been agreed that a comprehensive national organization or council of engineers should be created to be composed of representatives of local, state and regional societies. Further, that this organization be so framed as to include allied technical societies; and that cooperation of these several bodies in technical activities, and affiliations of local organizations for general public-service and welfare work be encouraged. This joint committee also recommends that the bill to create a National Department of Public Works receive the active support of all engineers.

Every thoughtful engineer will recognize the importance of these recommendations. The engineer has in the past been too much of an individualist. He is at heart a idealist. He lives in the things he creates, and often his chief reward is the satisfaction he enjoys from work well done rather than pecuniary. It is a splendid quality of heart and mind that enshrines the engineer. It harks back to those earlier days when respect for one's achievements and personal character measured success rather than the dollars amassed. But to keep one's place in these modern days requires that the game be played in accordance with prevailing rules. Thus the engineer must perforce conform to these rules if he would exert his fullest influence. It is organized rather than individual effort that gets ahead today. Only the individual who can direct and control organized effort stands out as an individual. He is the general in command of forces.

The one criticism of the engineering profession, as I see it, is that there are too few generals. The positions of high command too often go to others who are rarely themselves engineers but who constantly make use of engineers in framing and executing their plans. That is to say, the engineer, while he has the knowledge and skill required to plan and build structures utilizing Nature's material forces for the benefit of mankind, has appar-

ently given but little indication that he possesses the knowledge and skill required to handle human forces for the benefit of mankind. It would appear that that kind of leadership does not appeal to the engineer. He has made the instrument, even composed the music, which others have played to sway the multitude. In short, the engineer, if he has the qualities for leadership, has not been leading, except in his own field and amongst his own kind where of course he stands preeminent.

The world today needs a Moses to lead it out of the Wilderness. Moses must have been an engineer. That job of his in the Red Sea would indicate that he was an hydraulic engineer. Can the engineering profession aspire to such leadership as is today needed? No one knows. We think it can. But it would appear that the engineer has not been thought of in that connection. Why? Simply because he has in the past taken so little part in public affairs outside his profession. Here then lies the opportunity, the first step being to organize nationally and do the things recommended by our Joint Committee of the four national engineering societies.

One of the things recommended is the active support of the bill in Congress to create a National Department of Public Works. Such a department would at once bring the engineering profession before the eye of the world. It is such a normal and proper move that one would think it would carry itself. But it will not. You can be sure of that. It is forty years since the effort to secure such a department was first made. It failed as have all subsequent efforts for want of being properly pushed. And who is to push? You, gentlemen of the engineering profes-

sion. Not one, nor a few, but all of you and all together, and at this particular time.

I am now come to near the end of what I had in mind to say to you. There are other things that should be added to make my story of the year's doings complete. But something must be left for my successor in office to say next year. A president's address is not, I fear, the best medium of conveying a message to the multitude. It partakes more of the nature of an embalming process of ideas. It will find its mausoleum in the TRANSACTIONS. Some thousands of years hence it will be discovered, and the world of that day will comment on it much as we now do on the papyrus from the tombs of Egypt. But I have had great pleasure notwithstanding, in preparing my address.

Our worthy editor has for several weeks been keen to discover the title of my address. He was somewhat perturbed when I informed him that there was to be no title; that I proposed to be free, up to the last moment, to write what I pleased. The fact that I have succeeded in eluding him I consider some accomplishment, as you would agree did you know him as well as I do.

And now my adieux. It has been for me a happy year. I am grateful to you for your confidence, and your good will. It has brought forth the best that is in me. While I have many times failed to measure up to what I consider a proper specification for a president of The American Society of Mechanical Engineers, I have the satisfaction of feeling that I have stretched myself to the utmost in an effort to render all the service of which I was capable.

## WORK OF THE BOILER CODE COMMITTEE

*THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.*

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 228, 230, 252, 253, 256-261, inclusive, as formulated at the meeting of October 24, 1919, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

### CASE NO. 228

*Inquiry:* Will wrought-iron material made by the puddling process be acceptable under the Boiler Code Rules for use in superheater construction where the requirements in the Code specify wrought steel or cast steel?

*Reply:* Where the Boiler Code specifies wrought steel or cast steel for superheater construction, the intent was to prohibit the use of cast iron. It is also the opinion of the Committee that puddled wrought iron that will meet the requirements in the specifications for wrought iron in the Code will be a suitable material.

### CASE NO. 230

*Inquiry:* In the case of a water-tube boiler of the water-leg type, using large tapered connections from the rear header to the drum, is it permissible to weld the flanged edges of the water-leg sheets instead of butt-strapping them, and also the longitudinal joint of the tapered connection piece if it is amply braced cross-

wise by staybolts? These welded joints would not be under tension, as the staybolts take all of the pressure load and the possibility of breakage of these staybolts is negligible.

*Reply:* It is the opinion of the Committee that this cannot be done and comply with the requirements of the Code. The safety of the structure may be dependent upon the weld to the extent that the interior stresses in the weld, which would be relieved if rupture should take place, may throw suddenly upon the nearest staybolts, excess stresses which may cause the staybolts to fail in series.

### CASE NO. 252

*Inquiry:* Is it necessary under the requirements of Par. 186 of the Boiler Code, where door-hole flanges are to be welded and the stress due to the steam pressure is to be carried by the adjacent stay-bolting, to consider any limitation on the staybolt pitch to secure proper distribution of the load from the door-hole flanges to the staybolting?

*Reply:* It is the opinion of the Committee that under the requirements of Par. 186 the door-hole flanges of the furnace and exterior sheets may be joined by autogenous welding, provided these sheets are stayed or otherwise supported around the door-hole opening, and provided that the distance from the flange to the surrounding row of stays or other supports does not exceed the permissible staybolt pitch, as per Par. 199.

### CASE NO. 253

(Annulled)

### CASE NO. 256

*Inquiry:* Can a vertical fire-tube boiler be constructed with an unstayed furnace from 36 to 38 in. in diameter with butt-strap longitudinal seams as required in Par. 239 of the Boiler Code?

*Reply:* It was not the intent of the Boiler Code that the requirements for longitudinal seams of furnaces between 36 and 38 in. inside diameter should apply to the unstayed furnaces of vertical firetube boilers. Such furnaces over 36 in. inside diameter should be fully staybolted, as it is necessary to use lap-riveted longitudinal seams in this type of furnace. Butt-strap seams may be used only in horizontal furnaces where the seams can be placed below the grate.

## CASE NO. 257

*Inquiry:* Will a specially constructed water gage with an automatic-valve-closing device, arranged to be operated by a balanced pressure attachment depending for action upon the breakage of the water glass, be considered under the rules of the A.S.M.E. Boiler Code as an automatic water gage, in which the automatic shut-off valves must conform to the requirement of Par. 427?

*Reply:* It is the opinion of the Committee that the requirements of Pars. 292 and 427 of the Boiler Code apply specifically to automatic shut-off valves on water gages and not to exterior automatic devices which may be provided to close the valves. If the automatic closing device is not incorporated into the construction of the shut-off valves, the requirements of these paragraphs do not apply.

## CASE NO. 258

*Inquiry:* a In large hot-water heating boilers which under the requirement of Par. 335 of the Boiler Code must be constructed under the requirements for power boilers, is it necessary that such requirements as covered in Pars. 291 and 315 shall apply?

b Was it the intent of Par. 349 of the Boiler Code to cover the possible contingency of the necessity of a water-relief valve discharging steam, provided the boiling point has been passed, by the bursting of the diaphragm, thereby increasing the capacity of the water-relief valve?

c Would it be assumed that the safety of the structure would be dependent upon the strength of a weld made in a header of a Hawley down-draft furnace attached to the shell by means of pipe connections from each header, and could such a header be welded and a patch strap then applied over the top of the weld, to take the strain of a joint which is in tension?

*Reply:* a It is the intent of the requirement in Par. 335 that only such portions of the rules for power boilers shall apply to hot-water boilers as refer specifically to constructional details. The requirements for some of the fittings and trimmings for steam power boilers are obviously not applicable, so that in such cases the rules for hot-water heating boilers shall apply.

b It was not the intent of Par. 349 that the diaphragm of a water-relief valve should break after the valve opens.

c It is the opinion of the Committee that this is a question of repairing boilers. The Code gives certain recommendations in regard to the use of autogenous welding for repairs, but does not deal with the general subject of repairing which must, in each case, be taken up with the local state or municipal inspectors.

## CASE NO. 259

*Inquiry:* Is it allowable under the requirements of the A.S.M.E. Boiler Code to fit a high-pressure steam boiler with a 4-in. blow-off connection, in case it is to be used initially for low pressure steam service, or will it be necessary under the requirements of Par. 308 to apply two or more  $2\frac{1}{2}$  in. blow-off connections for the return connections to the boiler?

*Reply:* It is the opinion of the Committee that the boiler could be fitted with the 4-in. blow-off connection when in use for hot-water heating and, when converted to a steam boiler, a reducing fitting could be used at the 4-in. opening to reduce to the pipe size necessary for the blow-off connection.

## CASE NO. 260

*Inquiry:* Is the requirement of Par. 185 of the Boiler Code, relative to planing down the girth joint, applicable to a special type of boiler formed of an h.r.t. shell with a water-tube element over which the gases pass before coming in contact with the h.r.t. shell?

*Reply:* Par. 185 applies only to horizontal return tubular boilers and does not apply to a combination design of fire and water-tube boiler as described. In such a boiler the girth joints are not as directly exposed to the heat of the fire as in the case of the h.r.t. type of boiler.

## CASE NO. 261

*Inquiry:* What is the stress allowable under the requirements of the Boiler Code for unwelded solid stays more than 20 diameters in length?

*Reply:* It is the opinion of the Committee that the stress should be that given in item c in Table 5 of the Boiler Code, which is 9500 lb. where the lengths between supports do not exceed 120 diameters.

PROPOSED CODE FOR AIR TANKS AND  
PRESSURE VESSELS

For nearly a year a Sub-committee of the Boiler Code Committee has been engaged in formulating rules for the construction of air tanks and pressure vessels, to be known as Part I, Section IV, of the A.S.M.E. Boiler Code. It is the object of this section, which is devoted to pressure vessels other than fired steam boilers, to secure safe construction and at the same time to so establish the rules that the requirements are within practical working limits.

The work of the Sub-committee to which this task was assigned began in April, 1919, and the preliminary report which follows is the result of a careful and painstaking study. The Sub-committee consists of the following members:

E. R. Fish, <i>Chairman</i>	S. F. Jeter
Wm. H. Boehm	Wm. F. Kiesel, Jr.
C. E. Bronson	James Neil
E. C. Fisher	

The preliminary report was ordered printed by the Council of the Society with a view of having it discussed by the membership and the public at large. Discussions should be addressed to the Secretary of the Boiler Code Committee, 29 West 39th St., New York, N. Y.

A. S. M. E. BOILER CODE  
PART I—SECTION IVPRELIMINARY REPORT ON RULES FOR THE  
CONSTRUCTION OF UNFIRED PRESSURE VESSELS

*NOTE:* When this Section is incorporated in the Boiler Code, it will be desirable to add the words "AND OTHER PRESSURE VESSELS", at the top of the front cover and of the title page and on page 3 of the Code. Also the sentence in italics on page 3 will be changed to read, as follows:

*These rules do not apply to boilers and other pressure vessels which are subject to Federal inspection and control.*

Also to insert, after bracket in line beginning Part I, the following:

## SECTION IV—UNFIRED PRESSURE VESSELS

## DEFINITIONS

The vessels to which these rules apply are divided into two classes:

Class A—Vessels for containing liquids above the atmospheric boiling point, inflammable substances, or any gas, and limited in size to those over 6 in. in diameter, more than 1.5 cu. ft. in volume and carrying over 15 lb. pressure per sq. in.

Class B—Vessels for containing liquids, the temperatures of which are under control so as to be below atmospheric boiling point and limited in size to those over 9 in. in diameter, more than 4 cu. ft. in volume and carrying over 30 lb. pressure per sq. in. but not to exceed 100 lb. pressure per sq. in. For pressures over 100 lb. per sq. in. the rules for Class A vessels apply.

## MATERIAL

These vessels may be constructed of any metal complying with the following rules:—

The maximum allowable working stress used in any of the

metals selected shall be determined by the following formula:—

For Class A Vessels:—

$$S = 0.0125 E (e + 8) \text{ but not more than } 0.4 E$$

For Class B Vessels:—

$$S = 0.0125 E (e + 16) \text{ but not more than } 0.65 E$$

where

$S$  = Maximum allowable working tension stress, lb. per sq. in.;

$E$  = Elastic limit of material used;

$e$  = Elongation of material used, in per cent, in 8 in.

Working stress in rivets in single shear shall be taken as 80 per cent of  $S$ ;

Working stress in rivets in double shear shall be double that of single shear.

Staybolt values for allowable stress per sq. in. of net section shall be taken as follows:—

When  $e$  is not over 10 per cent = 60 per cent of  $S$ ;

When  $e$  is from 10 to 20 per cent = 70 per cent of  $S$ ;

When  $e$  is over 20 per cent = 80 per cent of  $S$ .

Class A Vessels may be constructed of materials specified in the A.S.M.E. Boiler Code (Edition of 1918), in which case the formula above given need not be used.

Class A Vessels shall be built in accordance with the rules of construction, which apply, of the A.S.M.E. Boiler Code (Edition of 1918) except Par. 186 which shall read as follows:—

The ultimate strength of a joint which has been properly welded by the forging process shall be taken as 65 per cent of the tensile strength of the plate.

and Par. 269 to 328, inclusive.

Class B Vessels may be constructed of material specified in the A.S.M.E. Boiler Code (Edition of 1918) in which case the formula above need not be used.

For Class B Vessels, steel of untested tank quality may be used, assuming the tensile properties below:—

Tensile strength, lb. per sq. in. .... 48,000

Yield point, lb. per sq. in. .... 25,000

Elongation in 8 in. .... 20 per cent

All Class B Vessels shall be constructed in accordance with the rules of construction, which apply, of the A.S.M.E. Boiler Code (Edition of 1918) with the following exceptions:—

Par. 180—change FS = 4.

Par. 186—rewrite as follows:—

The ultimate strength of a joint which has been properly welded by the forging process shall be taken as 65 per cent of the tensile strength of the plate. The ultimate strength of a joint which has been properly welded by the autogenous process, may be used in Class B pressure vessels only and shall be taken as 50 per cent of the tensile strength of the plate.

Par. 187—change 36 in. to 48 in.

Par. 188—change 36 in. to 48 in.

Par. 190—omit entirely.

Par. 195—change formula as follows:—

$$t = \frac{5 \times P \times L}{2 \times TS}$$

Par. 210—holes may be punched full size.

Par. 253—rewrite as follows:—

All rivet holes may be punched full size.

Par. 254—omit entirely.

Par. 256—omit entirely.

Par. 257—rewrite as follows:—

Calking shall be done with a round-nosed tool.

Par. 262—rewrite as follows:—

Manhole plates may be of wrought steel, steel castings or of cast iron.

Par. 263—omit entirely.

Par. 269-328—omit entirely.

No drain or blow-off shall be less than  $\frac{3}{4}$  in. pipe size.

**Safety Appliances.** All pressure vessels shall be provided with such relieving, indicating and controlling devices as the industry in which they are employed or use to which they may be put shall require to insure their safe operation. All such devices shall be

so located and installed that they cannot possibly be rendered inoperative. The relieving capacity of safety valves shall be such as to prevent a rise of pressure in the vessel of more than 6 per cent above the maximum allowable working pressure.

**Supports.** All vessels must be so supported as to equally distribute the stresses arising from the weight of the vessel and contents. Class A Vessels must be so arranged that the entire interior and exterior of the vessel may be thoroughly inspected. In the case of vertical vessels, the bottom head, if dished, of cylindrical vessels must be with the pressure on the concave side to insure complete drainage.

(Par. 325) Lugs or brackets, when used to support a vessel of any type, shall be properly fitted to the surfaces to which they are attached. The shearing and crushing stresses on steel or iron rivets used for attaching the lugs or brackets shall not exceed 8 per cent of the strength given in Pars. 15 and 16 of the Boiler Code.

**Corrosive Chemicals.** All pressure vessels which are to contain substances having a corrosive action upon the metal of which vessel is constructed should be designed for a pressure in excess of that which it is to carry to safeguard against early rejection.

Class A Vessels shall be stamped in accordance with the A.S.M.E. Boiler Code (Edition of 1918), Pars. 331-332.

Class B Vessels shall be stamped in accordance with the A.S.M.E. Boiler Code (Edition of 1918), Pars. 376 and 377.

{ A.S.M.E. }  
B

**Location of Stamps.** Location of tank manufacturer's stamps to be as follows: plain cylindrical tanks, and all other tanks not of a steam boiler type shall have at least one stamp, all stamps to be plainly visible when the tank is completed. On a tank with a manhole, said stamps shall be close to the manhole opening; on a tank without a manhole, close to the handhole; and on a tank without either a manhole or handhole, in a conspicuous place.

The tank builder's stamp shall not be covered by insulating or other material.

According to a recent article in *Oil News* the British-Inter-Departmental Committee on the production and utilization of alcohol for power and traction has recommended that the British Government study the possibilities of this form of fuel.

In the British Empire, according to the committee, there are vast prospective sources of alcohol in the vegetable world, although in the United Kingdom itself production from these sources is now and is likely to remain small. Synthetic production, however, especially from coal and coke-oven gases, is promising. The Committee also states in its report that "to the enormous growth of road motoring during recent years, especially in the United States of America, there will now be added the requirements of high-grade petrol for aeroplanes and airships, to which no limits can be assigned. Whilst it is impossible for us to forecast the development of total petrol consumption for all countries and all purposes, facts are not wanting to indicate the likelihood in the not distant future of so great a pressure of demand as to cause at any rate a very high level of prices, and we are satisfied that close investigation should now proceed with the object of providing alternative supplies of motor fuels derived from new or supplementary raw materials.

"We are satisfied that the time has come for government action, which should pay due heed to both current and prospective prices for petrol, or other petroleum products, benzol, and alcohol motor-fuel or its admixtures.

"We have received exhaustive technical evidence from representatives of the Ministry of Munitions concerning the investigations made by them during the war in respect of the extraction of ethylene from coal and coke-oven gases, and concerning quantitative results so obtained. The testimony of witnesses and records of work done indicate that there is available in Great Britain a large potential source of power alcohol, but further investigations are necessary in this connection, particularly as regards the conversion of ethylene into alcohol, before definite figures as to quantities and price can be given."

# ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

## Research on the Pacific Coast and at the Naval Experiment Station at Annapolis

**D**URING the past months the Committee on Research of the San Francisco Section has been active in sending out inquiries regarding research and the report below together with a letter of transmittal from Prof. W. F. Durand gives an excellent idea of research conditions in that portion of the United States.

When the Committee of the Society planned its present work it was not expected that we would receive information regarding research for private development purposes. This work in many cases represents a large expenditure of money and the Committee does not desire to publish any of this information until the proper time arrives. It has hoped that when such information is properly protected it will then be given to the profession as a contribution to our scientific knowledge.

The General Committee feels that the report of the San Francisco Committee is a most excellent one in bringing to our members problems on which work is being done and for which solutions are desired by engineers of the Pacific Coast.

The conditions for commercial testing at the Naval Experiment Station are described in a statement prepared from a note received from the Station. It is given here for the information of our members having apparatus or materials suitable for naval service.

LELAND STANFORD JUNIOR UNIVERSITY,  
STANFORD UNIVERSITY, CAL.,  
October 15, 1919.

PROF. ARTHUR M. GREENE, JR.,

Chairman, Committee on Research, A.S.M.E.,  
29 West 39th St., New York, N. Y.

MY DEAR PROFESSOR GREENE:

After some delay caused by the special rush of work at the opening of our academic year, I am handing you herewith a brief résumé of the replies received to date from the circular letters which we sent out regarding problems under investigation or suggested for research in San Francisco and vicinity.

Out of nearly two hundred letters sent out, only about a dozen replies have been received of sufficient significance to justify listing with reference to the purposes of the survey.

From what I learned by private conversation, however, it is perfectly clear that this is only a small part of the investigation and research work which is actually going forward. Many people stated that they did not feel at liberty to state the character of the work on which they were occupied, simply for the reason that they considered it confidential in character and of possible commercial value, and were, therefore, not disposed to make any report of the matter which might give any indication to other people, possibly competitors, regarding the work on which they are occupied.

I anticipated precisely some such result as this, although it was impossible to tell before the event just how much we might be able to develop under conditions involving commercial competition and the safeguarding of private interests.

It is evident that the amount thus actually developed by no means represents adequately the amount of research and investigation work on which mechanical engineers in this vicinity are occupied, but under the circumstances it seems to represent the best showing that can be made so far as a public record or statement is concerned.

I must confess to some doubt as to the extent to which our Committee can be of very much significance in connection with such work of research and investigation, due primarily to the disinclination of people to talk about work of this character, and the very natural desire to safeguard in every possible way personal and private interests. However, something useful may perhaps develop, and we shall always be glad to cooperate with the work of the general committee in so far as we possibly can.

Sincerely yours,

(Signed) W. F. DURAND.

SURVEY OF ENGINEERING RESEARCH, SAN FRANCISCO AND VICINITY  
PREPARED BY THE RESEARCH COMMITTEE OF THE SAN FRANCISCO SECTION  
OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

- 1 a Confidential metallurgical research work, the character of which cannot be made public.

- b Suggestion of the following subjects as important for investigations:

- 1 The development of a coke suitable for making pig iron on the Pacific Coast.

- 2 A continuous process for producing spelter.

A large part of our spelter is produced in Kansas and Oklahoma where natural gas used to be cheap. The old-style distillations furnace is used. Gas is becoming more expensive now and these furnaces are costly and wasteful. Zinc ore is produced largely in the west and it is a long haul to Oklahoma and Kansas. During the war some ore was shipped from Australia to the Kansas smelters. Electrolytic zinc is not as satisfactory a solution as had been hoped for.

Fuel gas can be obtained by partially coking the coal in a by-product oven so that the by-products would pay for the gas. Or pulverized coal might be used. It should not be difficult to devise mechanical means so that a continuous distillation could be obtained. This would eliminate the wasteful charging methods and the loss of time and retorts. Considerable study could be devoted to the production of a more satisfactory retort.

- 2 a Confidential developments relating to rotary gas compressors and the application of same to the various industrial uses such as: vacuum pumps, air compressors and refrigerating apparatus.

- b Suggestion of development of heating buildings by reversal of the thermodynamic cycle, using cheap electrical energy and low-temperature air as input with a delivery of high-temperature heat as output, measured in amount by the electrical input divided by the thermodynamic efficiency. Reference is made to Lord Kelvin's suggestion of possibilities along this line.

- 3 Investigation of certain forms of hydraulic dynamometers as a transmission device.

- 4 Development of a special or modified form of Diesel engine, cycle, intended to use kerosene and distillate. The special significance of this development lies in the possible extension of the use of kerosene or distillate for many purposes now requiring gasoline, and the resultant liberation of such amounts of gasoline for use in aeronautic and automobile engineering where the higher grades are especially desirable.

- 5 Development of proper type and mounting of ball bearings for deep-well and centrifugal pumps.

- 6 Development of a grade of steel suitable for pins for buckets on gold-dredging machinery. Pins vary in diameter from 3 in. to 7½ in. A few years ago a pin lasting nine months was considered as giving good service. With improved grades of steel, pins have now been in continuous service for three years.

- 7 Investigations on airplane propellers in connection with the National Advisory Committee for Aeronautics, the results of which are published in the annual reports of that Committee.

- 8 An investigation on the wear of gear teeth under loaded conditions, and including the influence of the following variable features:

- a Varying intensity of load

- b Varying materials

- c Varying tooth forms

- d Lubrication.

- 9 Investigation of the economic possibilities involved in the use of steel belting as a substitute for leather, and with special reference to the development of a satisfactory form of joint.

- 10 Research relating to the problem of the transfer of heat between fluids, vapors, and gases, and with special reference to the development of satisfactory commercial apparatus for such purposes, based on sound engineering principles. This research is intended to include a study of the transfer of heat between metal surfaces and fluids of widely varying viscosities and specific heats and including vapors and gases. In a detailed way the investigation will bear especially upon the transfer of heat between metallic surfaces and petroleum oils and water.

- 11 A general investigation relating to the problem of the development of a steam power plant, especially designed to meet the requirements of the self-propelled vehicle. This involves engineering research along the following lines:

- a A system of combustion, using for fuel kerosene and cheaper grades of fuel such as stove oil, etc. A successful system for this work requires complete combustion, as the formation of soot or carbon deposits would be objectionable.

- b In the construction of the combustion system, to make it entirely automatic and subject to control by boiler conditions, so that the temperature of the superheated steam, the pressure of the steam and the supply of feedwater to the boiler, would all be automatically controlled, so as to maintain uniform com-

ditions of operation. This involves the development of an automatic ignition device, so that by simply closing an electric switch, completing the circuit through the automatic control, the fire would be started under the boiler and brought under full control of the automatics to bring about the above results.

c A fuel and fire automatic control, so as to maintain within the boiler uniform temperature of superheat, of steam pressure and the necessary feedwater supply.

d The development of a new type of high-pressure boiler, especially developed to furnish steam at a high superheat, and at a maximum thermal efficiency.

e The development of a new type of steam engine which will have high economy, great flexibility of control and be able to utilize with maximum economy high-pressure steam with high superheat.

12 Investigations relating to improvements in electric furnaces, with special reference to the following applications:

a For the melting of steel scrap into steel castings.

b For the melting of steel scrap and ferroalloys into tool steels.

c The heat treating of steel castings, either annealing or tempering as the requirements may be.

d The melting of non-ferrous metals in commercial castings, particularly marine work.

## Commercial Testing at the Naval Experiment Station, Annapolis, Md.

The Bureau of Steam Engineering of the United States Navy conducts tests at its Naval Engineering Experiment Station of such engineering apparatus and materials as give promise of proving desirable for use in naval service. The requirements for making these tests are:

a That the material or device offered shall have definite application to naval needs.

b That the Government shall not be involved for any expense whatever either for the cost of the test, the material or apparatus tested, the shipment charges or damage to material or apparatus in consequence of the test.

c That the result of the test shall not be used for advertising purposes.

Application for test should be made in writing to the Bureau of Steam Engineering, U. S. Navy, Washington, D. C. If the nature of the article to be tested is not known or has not been explained in a personal interview the application must be accompanied by a complete description and blueprints, if necessary, for a thorough understanding.

If the test is authorized the applicant will be put into communication with the Superintendent of the U. S. Naval Academy, Annapolis, Md., who will furnish information as to any special requirements in connection with the test, such as number, size, and material of the article to be tested, steam pressure, etc., and will also designate the deposit which it will be necessary to make to cover the probable cost of test.

All necessary information having been received, the apparatus to be tested will be shipped, prepaid, addressed to the "Supply Officer," U. S. Naval Academy, Annapolis, Md., and plainly marked "For Engineering Experiment Station." A check will also be forwarded to the Superintendent of the Naval Academy, drawn to his order and covering the amount of deposit designated. Any unexpended portion of this deposit will be returned upon completion of the test.

The applicant will be allowed to have a representative present at all tests made on the apparatus submitted by him, and he or his representative may make suggestions or objections concerning the method of carrying out the test. Such suggestions will be followed so far as practicable and consistent with the purpose to obtain complete and conclusive data. The test authorities will be free to submit the apparatus or material to any test which in their judgment may be desirable to determine its suitability under any special requirements for use in the naval service, whether such tests have been contemplated by the applicant or not. When the applicant objects in writing to any proposed test on the ground that he believes the apparatus or material would be injured thereby, the particular test will not be made and the objection will be made part of the record of the test.

All applicants must agree in writing to accept the conditions

of the test set forth above and must further agree in writing that they will accept the results of the test as final and that they will not apply for a retest of articles or material until such changes have been made which will give reasonable promise of overcoming defects. This agreement in writing should be forwarded to the Superintendent of the Naval Academy together with the deposit mentioned in Par. 5.

Upon completion of test, a copy of the report thereon will be furnished the exhibitor by the Bureau of Steam Engineering.

For further particulars address Chief of the Bureau of Steam Engineering, Navy Department, Washington, D. C.

## A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulae or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigator do not warrant a paper.

*Electric Power A6-19.* Electric Ranges. C. W. Pieper is the author of a Bulletin No. 2 of the Engineering Experiment Station at Purdue University on electric ranges. Seven electric ranges were tested. The time taken to preheat the ovens and to heat 3 lb. of water within the oven to boiling point varied from 12 min. to 45 min., the oven temperatures varying from 420 to 530 deg. Fahr. On opening the oven doors for 45 sec. the temperature fell about 100 deg. Fahr. This was regained in about two minutes. The ovens required varying amounts of power to care for radiation. The most efficient oven required 100 watts to hold it at 200 deg. F., 300 watts for 395 deg., 500 watts for 550 deg. and 700 watts for 680 deg., while the less efficient oven required 220 watts for 200 deg., 610 watts for 395 deg., 1220 watts for 550 deg. The surface burners, which are in the form of porcelain hot plates, gave from 51 to 89 per cent efficiency in the evaporation of water, while in heating water the efficiency varied from 8 to 51 per cent. To bake biscuits about 1 kw-hr. is required. Cake requires 14/10 kw-hr.; bread 13/10 kw-hr. The following table gives the results for power supply of families of different sizes when the cost of power is 11 cents for lighting and 6 cents for the first 10 kw-hr. and 3 cents per kw-hr. beyond this. The form of load curve is given in Fig. 1.

Size of Family.	No. of Rooms.	Time, Month & Day.	Range, kw-hr.	Light, kw-hr.	Total, kw-hr.	Total Bill.	Net Range Bill.
2	6	1-14 to 2-21	36	11	47	\$2.29	\$1.19
3	6	3-24 to 4-24	71	11	82	3.96	2.16
3	7	1-22 to 2-21	112	20	132	5.06	3.06
5	6	3-22 to 4-22	64	58	112	4.24	1.56
7	8	2-23 to 3-24	104	32	136	5.31	1.11
7	10	2-21 to 3-21	108	51	159	6.53	1.43
7	10	12-22 to 1-22	167	57	218	8.30	2.60

The Bulletin describes the various ranges tested and discusses the advantage of electric ranges. Engineering Experiment Station, Purdue University, Lafayette, Ind. Address C. H. Benjamin, Director.

*Lubricants A2-19.* Cutting Oils from Machine Tools. Diseases have been caused by infections in cuts and abrasions in the skin of machine operators from oil used on machine tools. This has been the subject of a report by Lieutenant-Commander A. G. Zimmermann of the Ordnance Department, U. S. Navy. His report quotes Bulletin No. 2 of the Department of Scientific and Industrial Research, No. 15 Great George St., Westminster S.W.-1, London, England. This Bulletin is a memorandum on Cutting Lubricants and Cooling Liquids, their Purposes, Properties, Composition, and the second part of the paper is on the Skin Diseases caused by Lubricants.

Oil rashes are caused by:

(a) The plugging of glands of the hair follicles.

(b) Mechanical injury to the skin by metallic particles.

Any injury to the skin may allow germs to enter and cause septic infection. To prevent disease the workmen must keep perfectly clean, washing with hot water and soap and scrubbing brushes and not washing in the cutting compounds. The lubricant must be kept clean by constantly removing the metal particles by filtration and the machines must be kept clean by frequent removal of all old lubricant and dirt. The lubricants should be treated with disinfectants or antiseptics, although the use of some of these promote skin poisoning. It is well to sterilize the cutting oil by heat, and 300 deg. Fahr. is suggested for the temperature of this heat. Any workers with septic infection of the hands should not be permitted to work. Workmen should be instructed to refrain from expectorating in the pans of the machines. The treatment for the blocking of the glands is frequent washing with soap and water followed by the use of zinc oxide and starch powder. Septic infections in cuts should be treated by suitable

antiseptic dressings. Certain persons are more susceptible than others.

This report may be obtained from the Department of Scientific and Industrial Research, London, England.

Commander Zimmermann also quotes from the "Traveler's Standard" of July, 1918, prepared by the Engineering and Inspection Division of the Travelers' Insurance Company. This article speaks of the contamination of the oil from sputum. The report suggests repeated heatings to kill the germs and also repeated cleanings of the system. The dressings used for cuts should be such that the oil cannot further enter the broken skin. For that reason a colloid dressing may be quite useful. In many cases a rubber cut is advantageous.

One per cent of carbolic acid may be added as a germicide, but an excessive amount of acid will cause poisoning. It must be remembered that workmen have their hands wetted with the cutting fluid for hours at a time. Tanks used to hold the cutting oils should be covered so that animals may not drop in and become decomposed.

An investigation of oil samples from a machine tool showed the presence of bacteria found in sputum. It is important that notices against spitting in oil pans should be posted.

FIG. 1 FORM OF LOAD CURVE OF ELECTRIC RANGE

FIG. 2 BOTH CRUSHING STRENGTH AND MERCURY CONTENT OF AN AMALGAM VARY AS LOGARITHM OF PACKING PRESSURE. LARGE DEVIATIONS FROM LOWER CURVE ARISE FROM CRUSHING SPECIMENS AT VARIOUS TEMPERATURES

**Marine Engineering A1-19.** The Propulsive Efficiency of Single-Screw Cargo Ships. A comparison of hulls of longitudinal coefficients of 0.74, 0.76, 0.78, 0.80 and 0.82 and of the same overall dimensions. The parallel middle body should be about one-third of the length as determined in a previous test, but in these tests the parallel portion of the ship was made longer. The model was tested by self-propulsion, using a floating form of dynamometer to get torque, while thrust was measured by a spring attached to the thrust bearing, and revolutions of the shaft were measured by suitable means. The model was also tested from the towing carriage. With speeds up to 7 knots there was little variation in power, but the resistance in the ships with the higher longitudinal coefficient the increase of power was much greater than the increase in displacement. This would not prevent the use of the ships with the longer parallel section where cargo capacity is

important. The general conclusion of the experiments is that for a well-designed hull with a propeller running at about 90 r.p.m., a hull efficiency of 1.09, a propulsive efficiency of 0.65 may be expected from single-screw cargo ships. This paper was read at the General Meeting of the Society for Naval Architects and Marine Engineers, Nov. 13, 1919, by Commander William McEntee, Construction Corps, U. S. Navy, Washington, D. C.

**Metallurgy and Metallography A20-19.** Copper Content in Steel. A report is made from the Bureau of Ordnance of the Navy Department that the Metallurgical and Testing Division have made experiments on steel in which the copper content was increased to as much as 2 per cent. The gun factory has been manufacturing nickel steel with copper contents between 0.4 and 0.7 per cent, and when properly handled these steels showed a marked superiority for most purposes over steel free from copper. The gun factory has not found that steel containing appreciable amounts of copper when properly made is more red-short than steel of similar quality free from copper. With poorly made steel red-shortness may be found.

In successfully manufactured steel containing an appreciable amount of copper, precaution must be taken to prevent the copper from liquating or separating during solidification as the solubility of copper is not as great in ternary alloys as in the case of other alloying elements. The usual practice in the gun factory is to keep the manganese content of the steel slightly higher when the alloy carries an appreciable amount of copper. The higher manganese content tends to hold the copper in perfect alloy and prevent the tendency to red-shortness due to the presence of slightly excessive amounts of sulphur. Steel with 2 per cent copper shows most excellent physical properties when liquation was prevented by rapid solidification of the ingot through a low pouring tem-

FIG. 3 EFFECT OF TEMPERATURE ON CRUSHING STRENGTH. TRANSITION REGION IS SHOWN BY THE RAPID FALL IN STRENGTH BETWEEN 70 DEG. AND 80 DEG.

perature and by use of a very heavy chill. Report by Lieutenant Commander A. G. Zimmermann, U. S. Navy. Address Rear Admiral Ralph Earle, Chief of Ordnance, U. S. Navy, Washington, D. C.

**Metallurgy and Metallography A21-19.** Bronze. Effect of Boiling Bronze in Oil. The Bureau of Construction and Repair of the U. S. Navy reported that test bars of manganese bronze were being boiled in oil to improve the physical characteristics. This matter was investigated by the Metallurgical and Testing Division of the Ordnance Department of the U. S. Navy under the direction of Lieutenant-Commander A. G. Zimmermann. Although there was no reason to expect any decided change under these conditions four block test bars were taken and two specimens were machined from each block. One of each was boiled for one-half hour in sperm oil at a temperature of 150 deg. Fahr. The physical qualities of the treated and untreated bars are given below to show that this treatment has no effect on the physical qualities of manganese bronze:

Not Treated.			Treated.		
Yield Point.	Tens.	Elong.	Yield Point.	Tens.	Elong.
46,100	76,400	21.75	50,400	76,400	22.00
42,900	73,200	25.50	47,900	73,900	25.50
44,400	72,400	23.25	43,900	75,000	23.50
49,400	79,500	18.75	47,900	79,800	18.50

Address Bureau of Ordnance, U. S. Navy. Rear-Admiral Ralph Earle, Washington, D. C.

**Metallurgy and Metallography A22-19.** Amalgams. The tests of dental amalgams formed by making an amalgam of mercury with an alloy of silver, tin and other metals has shown that the strength of the amalgam after hardening forms a logarithmic function of the pressure used in packing the amalgam and also the mercury content of this amalgam is a similar function. This is shown in Fig. 2.

The tests also show that there is a gain in strength due to the time of trituration, the maximum strength occurring at this time in six minutes. Temperature decreases the strength of an amalgam as shown in Fig. 3.

The amalgams change in volume during the time of hardening. This change in volume is called reaction expansion. They have been measured by a dilatometer capable of measuring to 1/500 micron. With heavy packing pressure the time to reach the maximum or minimum expansion is decreased. Increasing the trituration time accelerates the time of reaching the maximum pressure. Reducing the temperature retards the action. Time of packing does not have much effect. The amount of expansion is influenced by the time used in annealing the alloy for the amalgam. The greater the time of annealing the greater the reaction expansion. These results are of value to the mechanical engineer in that they are phenomena which occur in alloys not far removed from their melting points. These results are given in a paper by Arthur W. Gray, Ph.D., in the Transactions of the American Institute of Mining Engineers for December, 1918, Address Dr. Arthur W. Gray, L. D. Caulk Dental Company, Milford, Del.

#### B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

**Fuels, Gas, Tar and Coke B9-19.** Gasoline from Heavier Oils. A series of experiments have been made by E. W. Dean at the Bureau of Mines Station, Pittsburgh, Pa., in which a study was made of the cracking reactions for conditions favorable for transformation of heavier oils into gasoline. Bureau of Mines, Washington, D. C. Address Van H. Manning, Director.

**Fuels, Gas, Tar and Coke B10-19.** Oil Shales. The Bureau of Mines is investigating the retorting of oil shales and the crude oils obtained therefrom. This work is under the direction of W. D. Bonner and M. J. Gavin, Bureau of Mines, Washington, D. C. Address Van H. Manning, Director.

**Lubricants B9-19.** Analytical Distillation of Emulsified and High Boiling Oils by E. W. Dean, Pittsburgh, Pa. Bureau of Mines, Washington, D. C. Address Van H. Manning, Director.

**Metallurgy and Metallography B16-19.** Manganese Ores. The Bureau of Mines is investigating the mining and concentration of ores for the purpose of utilizing low-grade ores and the improvement of methods of mining. Bureau of Mines, Washington, D. C. Address Van H. Manning, Director.

**Petroleum, Asphalt and Wood Products B1-19.** Petroleum, Conservation and Production. The Bureau of Mines is conducting at its stations in Bartlesville, Okla., and San Francisco, investigations relating to petroleum conservation and production. The various headings are as follows:

- Water Problems
- Decline of Oil-Well Production
- Oil Storage and Transportation Losses
- Oil-Well Cements
- Mode of Occurrence of Oil, Gas and Water in Underground Strata
- Oil Casing, Perforation and Screen Pipes
- Cement Oil Wells
- Oil Camp Sanitation
- Transporting Heavy Oils
- Factors in Oil Production
- Oil-Well Drilling on Government Lands
- Transmission of Probable Depreciation
- Methods of Increasing Production
- Legislation
- Construction and Operation of Oil Storage Facilities
- Oil Shale
- Circular Method of Oil-Well Drilling
- Bureau of Mines, Washington, D. C. Address Van H. Manning, Director.

**Petroleum, Asphalt and Wood Products B2-19.** Examination of American Crude Petroleum. A study of physical and chemical properties of American crude petroleum by (1) routing comparison of relatively large number of samples. (2) A detailed study

of a smaller number of representative composite samples by E. W. Dean, Bureau of Mines Station, Pittsburgh, Pa. Address Bureau of Mines, Washington, D. C. Van H. Manning, Director.

**Ventilation B1-19.** Ventilation of Metal Mines. The Bureau of Mines is reporting through Daniel Harrington the investigations on the ventilation of the Butte mines. The report will discuss the underground and surface conditions affecting the flow of air and its adequate distribution. This will be discussed in its application to general principles. Bureau of Mines, Washington, D. C. Address Van H. Manning, Director.

#### C—RESEARCH PROBLEMS

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

#### D—RESEARCH EQUIPMENT

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

**Kansas State Agricultural College D2-19.** Thermal Testing Plant. The refrigerating equipment: 2-ton experimental steam-driven refrigerating system of direct expansion, compression type and duplicate 1-ton electrically-driven system. Calorimeter room 9 ft. x 12 ft. x 10 ft., built of cork board and equipped with 600 ft. of 2-in. direct-expansion piping. The quantity of ammonia circulated together with temperature regulation is controlled through expansion valve and speed of compressor. Temperature regulated within 1/2 deg. Fahr. Test boxes are cubes of 2 ft. in diameter. Three boxes are being used; one of 3-in. cork board, one of 3-in. waterproof lith board and one of 2-in. waterproof lith board. The boxes are heated electrically by special alloy resistance coils placed within each box. Three coils are used in each box. The current is supplied by 12-volt storage battery, being regulated by variable external resistance.

The temperature is measured by electric pyrometers accurate to 1/5 deg. Fahr. These are thermocouples of No. 16 gage copper-constantan wire and are connected to the potentiometer indicator by a multiple switch. The cold end of the thermocouple is inserted in a vacuum bottle containing a liquid, the temperature of this liquid being measured by means of a mercury thermometer.

There is no fan within the test box. The heat through the top and bottom is figured separately from the heat through the sides by determining temperature difference of various surfaces.

It is hoped that investigations will throw light on heat transmission due to radiation as well as that due to convection. It is also planned to determine, if possible, the relation between temperatures at various points in the interior of the box and the heat transmitted per sq. ft. through the material.

**Massachusetts Institute of Technology D1-19.** Electrical Engineering Laboratory. The laboratories of the Department of Electrical Engineering of the Massachusetts Institute of Technology are four in number, their purposes and equipments being as follows:

The **Electrical Measurements Laboratory** is equipped for the general problems of electrical testing and electrical measurements including standardization. Insulating materials may be tested for dielectric strength of 100,000 volts and also special equipment for measuring losses of energy in dielectric when subject to alternating voltages.

The **Dynamo Laboratory** is equipped with instruments and apparatus necessary for problems relating to dynamos and special problems of losses in iron when subject to magnetization under various conditions of the form of test piece, the frequency of alternations of magnetism and variations of magnetic density.

The **High-Frequency Laboratory** is equipped with alternators giving alternating currents of 10,000 periods per second and 100,000 periods per second, also with kenotrons and other tuned devices for obtaining alternating currents of controllable frequencies and amounts. This laboratory offers excellent opportunity for studying special problems of radio telegraphy, and telephony as well as problems of skin effect in conductors when currents flow through them.

The **General Research Laboratories** are equipped with artificial lines representing certain conditions of very long-distance power-

transmission lines and of telegraph and telephone lines and some of the characteristics of real lines have been traced out. The equipment includes instruments for measuring tractive effort, for studies of motor transportation and street-railway transportation, hot-wire ammeters, sensitiveness of oscillographs and the characteristics of diaphragms.

The Department has published twenty bulletins after their publication as papers presented to the American Institute of Electrical Engineers, numbered as follows:

- 1 The Economical Transportation of Merchandise in Metropolitan Districts.
- 2 Notes on the Cost of Motor Trucking.
- 3 Observations on Horse and Motor Trucking.
- 4 Relative Fields of Horse, Electric and Gasoline Trucks.
- 5 The Delivery and Handling of Miscellaneous Freight at the Boston Freight Terminals.
- 6 The Delivery System of R. H. Macy and Co. of New York.
- 7 Explorations over the Vibrating Surfaces of Telephonic Diaphragms as Derived from their Motional-Impedance Circles.
- 8 The Mechanics of Telephone-Receiver Diaphragms as Derived from their Motional-Impedance Circles.
- 9 Experimental Researches on Skin Effect in Conductors.
- 10 Tractive Resistances to a Motor Delivery Wagon.
- 11 Some Properties of Vibrating Telephone Diaphragms.
- 12 Experimental Researches on the Skin Effect in Steel Rails.
- 13 Skin-Effect Resistance Measurements of Conductors at Radio-Frequencies up to 100,000 Cycles per second.
- 14 Street Railway Fares; their relation to length of haul and cost of service.
- 15 Apparent Dielectric Strength of Varnished Cambric.
- 16 Magnetic Flux Distribution in Annular Steel Laminæ.
- 17 Electromagnetic Theory of the Telephone Receiver with special references to Motional Impedance.
- 18 A Rectangular-Component Two-Dimensional Alternating Current Potentiometer.
- 19 Current Distribution in Armature Conductors.
- 20 Alternating-Current Planevector Potentiometer. Measurements at Telephonic Frequencies.

**Mellon Institute D2-19.** The Mellon Institute of Industrial Research is equipped for engineering research as well as that in pure and applied science. The following equipment is available for engineering work:

Two 100-hp. Sprague electric dynamometers equipped with revolution counters operated by the same electric circuit.

A three-section pipe arranged so that there is no end transmission of heat from the electric heaters on the inside of the middle section.

One standard Dodge automobile 4-cylinder gas engine connected to 75-hp. Sprague electric dynamometer equipped with automatic test timing device actuated by fuel-weighting scale.

Gas producer of modern mechanical type  
Complete grinding and pulverizing machinery  
Well-equipped machine and woodworking shop  
Sweetland filter press  
Vacuum dryer  
Furnaces for refractory and ceramic research  
Lummus column still.

**Refrigeration D3-19.** Thermal Testing Plant. See Kansas State College, D2-19.

#### E—PERSONAL NOTES

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

**United States Naval Experiment Station E1-19.** The work of the U. S. Naval Engineering Experiment Station at Annapolis, Md., consists of the following:

- a Determination of conformity to specifications issued by the Bureau of Steam Engineering for particular materials or machines.
- b Establishment of an "improved list" for the purchase of types and makes of materials and appliances coming under the cognizance of the Bureau of Steam Engineering.
- c Determination of the most satisfactory of a number of devices as regards efficiency, performance, or other operative peculiarities.
- d Obtaining data for the basis of specifications for the purchase of material or the modification of existing specifications.
- e Furnishing the Bureau of Steam Engineering with design data and methods of design for various kinds of apparatus for which the existing data and methods are either insufficient or unsatisfactory.

f Investigation of new machines or materials and, if necessary, the development of them into practical form.

g Discovering the cause of failure or of poor performance in order to recommend to manufacturers and to the Bureau of Steam Engineering, alterations which will fit the apparatus or material under test for use in naval service.

h Regular courses of instruction to classes of student officers from the Post Graduate School, U. S. Naval Academy, and to undergraduate midshipmen from the U. S. Naval Academy.

There are three laboratories: the Engineering Laboratory, the Chemical Laboratory and the Metallographic Laboratory. In the Engineering Laboratory the following items are included:

Internal-combustion engines,  
Refrigerating apparatus,  
Condensers, air pumps, blowers, fans and air compressors,  
Steam turbines,  
Heaters for feedwater, fuel oil and lubricating oil,  
Evaporators, distillers, pumps, rotary engines,  
Safety valves,  
Steam traps,  
Pump valves,  
Sheet and rod packings,  
Boiler fittings,  
Blow valves,  
Water columns,  
Gage glasses,  
Feedwater regulators,  
Stop and non-return valves,  
Pump governors,  
Pressure-regulating valves.

The work of the Chemical Laboratory is divided into several parts:

a All oils submitted for use in the naval service are tested in this laboratory and from the results of the tests recommendations are made to the Bureau of Steam Engineering for their approval or rejection.

b Analyses are made of boiler compounds, fuels, boiler deposits, boiler waters and all other materials as requested by the Bureau of Steam Engineering.

c New processes for production of hydrogen for aviation are proposed and developed.

d All problems in lubrication for the United States Navy are taken up in this laboratory.

e The chemical features of many problems connected with the operation and maintenance of naval machinery are investigated.

The work done in the Metallographic Laboratory consists of the following:

a Investigation of the cause of failure of metals in naval service, including shafting, boiler tubes, boiler plates, condenser tubes, gland rings, studs, metallic packing.

b Research with the view of determining the suitability of new alloys or new metallurgical methods for adoption in the Navy. These include bearing metals, aluminum alloys, nickel, silver and aluminum solders, welding methods, etc.

c Inspection tests, including metallographic inspection of forgings intended for naval service.

d Miscellaneous tests involving investigations for the preparation of specifications, standardization of tests, etc.

e Instruction of post-graduate students and undergraduate students of the Naval Academy.

#### F—BIBLIOGRAPHIES

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file in the offices of the Society.

**Boilers and Accessories F3-19.** Feedwater Evaporating Equipment. A bibliography of 134 pages. Search 2731. Address A.S.M.E., 29 West 39th St., New York.

**Cement and Other Building Materials F1-19.** Sand, Its Occurrence, Properties and Uses. A 72-page bibliography prepared by the Pittsburgh Carnegie Library. Price 15 cents. Address Director of the Carnegie Library, Pittsburgh, Pa.

**Properties of Engineering Materials F2-19.** Determining, Producing and Maintaining Hardness of Metals. A bibliography of 28 pages. Search 2683. Address A.S.M.E., 29 West 39th St., New York.

**Properties of Engineering Materials F3-19.** Design and Strength of Riveted Joints. A bibliography of 8 pages. Search 2740. Address A.S.M.E., 29 West 39th St., New York.

## BUREAU OF STANDARDS

**STORAGE-BATTERY TESTING.** In the operation and testing of storage cells, it is frequently important to know the individual potentials of the positive and negative plates. No standard method has been recognized. The results obtained with the cadmium electrode are often contradictory. This investigation has been made to determine the reliability of the cadmium electrode and the errors in measurement to which it is subject. The standard electrode used was the mercurous sulphate half-cell. It was found that the most serious error in using the cadmium electrode is due to polarization. By measuring the potential of the negative plate and computing the potential of the positive plate from this and the cell voltage, the most serious error of the cadmium electrode can be avoided, even when using an ordinary voltmeter. This investigation deals only with the accuracy of the cadmium electrode and does not discuss the cadmium readings with reference to the age or condition of the battery. (*Bureau of Standards Technologic Paper No. 146, entitled The Cadmium Electrode for Storage Battery Testing, g*).

## Annual Report of Bureau of Standards

**ANNUAL REPORT OF THE DIRECTOR OF THE BUREAU OF STANDARDS.** A review of the work of the National Bureau of Standards for the year ended June 30, 1919, is given in the annual report of the Director of the Bureau of Standards at Washington. The report describes the functions of the Bureau of connection with standards and standardization, and contains a chart and description of the several classes of standards dealt with. The Director also gives a clear idea of the relation of the Bureau's work to the general public, to the industries, and to the Government, and includes a special statement of the military work of the year. Brief statements are made upon practically all of the special researches and lines of testing completed or under way at the Bureau. The list of these topics occupies 12 pages in the table of contents.

The Bureau is organized in 64 scientific and technical sections and 20 clerical, construction, and operative sections. During the year the Bureau has issued 51 publications, not including reprints, 36 of which were new and 15 revisions of previous publications. In the several laboratories of the Bureau more than 131,000 tests were made during the year. The appropriations for the year, including special funds for war investigations, were approximately \$3,000,000. A noteworthy event of the year included the completion of the industrial laboratory in which will be housed the divisions having to do with researches and tests of structural materials. The building also includes a commodious kiln house for use, among other purposes, of the ceramics division in the experimental production of new clay products and for general experimental purposes.

The report comprises 293 pages, and may be obtained as long as free copies are available by addressing the Bureau of Standards, Washington, D. C. (Abstract of *Miscellaneous Publication of the Bureau of Standards, No. 40, g*)

## ENGINEERING MATERIALS (See also Internal-Combustion Engines)

**THE PROPERTIES OF AMERICAN BOND CLAYS AND THEIR USE IN GRAPHITE CRUCIBLES AND GLASS POTS, A. V. Bleining.** The properties of American bond clays are described in detail and expressed through characteristic numerical values, with special reference to their burning behavior. It is shown that materials equal in quality to those formerly imported from Germany are available, and that by suitable blending any desired combination of properties can be readily produced. The characteristics of natural and artificial graphite are described and means suggested for the control of crucible mixtures. The fact is brought out that the main advantage in the use of German glass-pot clay consists in its low shrinkage, and suggestions are made for obtaining similar conditions with the use of domestic materials and with increased resistance to corrosion. The compositions and the preparation of semi-porcelain and porcelain glass pots are given. The method of casting glass pots as practiced at the Pittsburgh laboratory of the Bureau of Standards is also described. (Abstract of *Technical Paper 144, U. S. Bureau of Standards, g*)

## FUELS AND FIRING

**FUEL-ECONOMY REPORT OF THE BRITISH ASSOCIATION.** The report consists of several parts. The first part outlines the work of the Committee since 1916. The second part deals with coal output and prices since 1913. The third part (on Coal Research) states that the recent experiments by Bone and Sarjant make it very doubtful whether the resinous and cellulose constituents of coal can really be separated by the aid of pyridine and chloroform. It would appear that pyridine affects the coal substance as a whole, especially at higher temperatures and pressures, while the presence of water and oxygen retards the action.

The last part of the report is devoted to the subject of future standards of public gas supply. The Committee believes that the consumer should be supplied with a suitable gas for lighting and heating, while the recovery of by-products should be secured in the general interest. It would not exclude the distribution of surplus of coke-oven gas through the pipe mains and the steaming of incandescent coke in continuous vertical-retort working; but it would not oblige a gas coke to convert all its coke into water gas. The Committee would not admit further that the relative value of a grade of gas was simply proportional to its calorific

value. The composition of the gas was not an indifferent matter to the consumer—in particular, the percentage of  $\text{CH}_4$  should not be reduced below 30; also, to strip the gas of benzenoid hydrocarbons seemed inadvisable, if the thermal basis were to be adopted. (*Engineering*, vol. 108, no. 2809, Oct. 31, 1919, pp. 574-576, *g*)

**FUEL-OIL SITUATION IN THE EAST.** An editorial article in *Power* touches upon the important change in the fuel used in large power plants in the Eastern States which has been gradually taking place in the last few years. One after another important plants have displaced coal in favor of fuel oil. This has been natural for several reasons. In the first place, the coal market was anything but attractive to the buyer, both as regards prices and conditions of supply. Also fuel oil is a more convenient fuel to handle, increases boiler and fuel efficiency and greatly cuts labor costs and troubles. On the other hand, the editorial calls attention to the very important fact that there appears to be no certainty that oil will be available for long periods as it is available today, even though three- to five-year contracts are possible. (*Power*, vol. 50, no. 17, Oct. 21, 1919, published Dec. 1, 1919, pp. 623-624, *g*)

## HYDRAULIC ENGINEERING

### Photographic Method of Determining Velocity of Flow of Liquids

**DETERMINATION OF VELOCITY OF FLOW OF LIQUIDS, C. Camichel.** An article describing the method of determining the velocity of flow of liquid by the observation of the travel of very fine particles carried along by the liquid.

This method was employed for the first time by Scott Russell. The author, who is the director of the Electrotechnic Institute of Toulouse, France, indicates briefly some of the results which have been obtained by applying this method to various hydrodynamic problems.

**I. Flow of Water between Two Vertical Parallel Plates, such as Glass.** The  $x$  axis is horizontal and parallel to the plates; the  $y$  axis is horizontal and normal to the plates; the velocity of

FIG. 1. CURVE DISTRIBUTION OF VELOCITIES IN FLOW OF WATER BETWEEN TWO PARALLEL PLATES

flow  $u$  satisfies the relation resulting from the equation of Navier

$$\mu \frac{d^2 u}{dy^2} = \frac{dp}{dx} \dots \dots \dots [1]$$

where  $p_0$  is the hydrostatic pressure;  $p + p_0$  the pressure during the flow,  $p$  being a function of  $x$  only.

The following are some data obtained experimentally. The water flows between two parallel vertical glass plates located at a distance of 2 cm. from each other, the plates themselves being 30 cm. (11.8 in.) wide and 4 m. (13.1 ft.) long. The experiment consists in lighting up horizontally very fine particles suspended in the water by using a luminous batch of rays interrupted by a toothed wheel rotating at a constant speed, and in taking photographs by means of a camera placed at a point on the horizontal median plane.

A number of illustrations reproducing the photographs thus obtained are given in the original article, but they are not distinct enough for further reproduction. A very careful examination of these photographs shows that the reflection on the glass of the trajectories of the particles makes it possible to determine with considerable precision the values of  $y$  measured from one of these walls. Table 1 gives data obtained from one such test. It is easy to see that the curve  $(u, y)$  is a parabola and it is enough to plot a curve with ordinates  $du/dy$  and abscissæ  $y$  to see that such a curve is a straight line. This has been done in Fig. 1.

If we take as a coefficient of viscosity of the water  $\mu = 0.011$  in C.G.S. units for the temperature prevailing during the experiment (16 deg. cent.), we get

$$\mu \frac{d^2 u}{dy^2} = 0.0005 = \frac{dp}{dx}$$

The value of the loss of head  $W$  for two points located on a line parallel to the axis of  $x$  and at a distance of 80 cm. from each

FIG. 2. DISTRIBUTION OF VELOCITIES IN A GYRATORY MOVEMENT

other, we find to be  $W = 0.05$  mm. Though it is difficult to find the correct value of such a small loss of head, it can be measured by means of the M. R. Threlfall manometer with a micrometric screw; this gives for  $W$  the value of 0.07 mm., which is in sufficiently good accord with the formula above.

The above experiment has been carried out with the velocity

FIG. 3. DISTRIBUTION OF VELOCITIES IN A GYRATORY MOVEMENT

of flow of water reduced as far as possible, but similar experiments have been carried out for very much higher velocity.

**II. Gyratory Movement about a Vertical Axis.** In studying rotary movements accompanying flow of liquids from orifices, Boussinesq has shown that if one limits himself to the consideration of the superficial particles of the liquid the velocity of flow is proportional to the distance  $r$  from the axis, in the part where the trajectories of flow are approximately horizontal, so that

$$ur = C. \dots \dots \dots [2]$$

Fig. 4 MERIDIAN OF GYROTORY MOVEMENT

This is roughly shown in Fig. 2 which demonstrates the distribution of velocities of flow in a gyrotory movement about the vertical axis. Table 2 gives in numerical form the results of a similar experience;  $\alpha$  designates the angle formed by the rays passing through two extreme positions of a particle at the beginning and end of a photographic exposure.

Fig. 3 represents the curve having for its abscissa  $1/r^2$  and for its ordinates  $\alpha$ . It is a straight line. The angular velocity varies therefore inversely as the square of the distance of the particle from the axis, and hence the linear velocity varies inversely as the distance from the axis, in accordance with Formula [2]. If we apply the theory of Bernoulli and designate by  $h$  the depth  $z_0 - z$  of the free surface below the horizontal plane containing the limit of the vortex of radius  $r_0$ , which is very large, we have approximately

$$h = \frac{C^2}{2g} \frac{1}{r^2} - \frac{1}{r_0^2} = \frac{C^2}{2g} \frac{1}{r^2} \dots \dots \dots [3]$$

The experiment consisted in photographing the meridian of the gyrotory movement, that is, the curve having for its abscissa  $r$  and for its ordinates  $h$ , Fig. 4, and also the distribution of velocities shown in the original article in a figure not suitable for reproduction.

In this experiment 100 mm. of the caliber occupied 108 mm. on the photographic plate, the periods of interruption of the ray of light being 0.026 sec. The meridian of the gyrotory movement is given in Table 3 for points which are not too close to the axis.

The curve with abscissa  $\frac{1}{r^2}$  and ordinates  $z_0 - z$  is a straight line

for points which are not very close to the axis, as shown in Fig. 5. The angular coefficient of this straight line is

$$\frac{C^2}{2g} = 4.1 \times 10^{-1}$$

and the distribution of the velocities gives

$$\frac{C^2}{2g} = 4.2 \times 10^{-1}$$

a value in good accord with what has been given above.

In the preceding experiment the gyrotory movement was counter-clockwise. There is, however, no difference between the

Fig. 5 MERIDIAN CURVE OF GYROTORY MOVEMENT

clockwise and the counter-clockwise movements. It is intended to carry out an investigation of the distribution of velocities in the neighborhood of the axis and in the interior of the liquids. (*Revue Générale de L'Electricité*, vol. 6, no. 21, Nov. 22, 1919, pp. 707-709 and 2 plates, 8 figs., et al.)

### Water Turbine with Two Pelton Wheels of Different Diameters

ITALIAN WATER TURBINES, Norman Davey. First of a series of articles entitled Notes on a Tour in Italy and France, devoted chiefly to the description of hydraulic machinery.

In the Riva (Milan) type of larger turbines particular attention is called to the oil-pressure thrust block. The end thrust of the rotor is taken up by oil pressure upon the surface of a disk attached to the turbine shaft; oil under pressure is circulated on both sides of the disk and an equilibrium of thrust is thus secured.

Mention is made of a rather unusual type of turbine which the author has seen in the process of construction. It is to be used to produce power for the Italian Electric State Railways. The machine consists of two Pelton wheels of different diameters, employing varying heads of water, the water in question being drawn from two different sources of supply. Of the two wheels which are upon the same shaft, one is operated by a head of 2000 ft. and the other of 670 ft. As a large variation of load occurs throughout the 24 hr., the plant is fitted with an automatic device by means of which the smaller wheel, which is only used when the load rises to a certain point, may be put to work. The diameters of the two wheels taken at the centers of the buckets are 6.4 ft. and 3.67 ft., respectively, and the speed 500 r.p.m. The larger diameter wheel develops 3500 hp. with one jet and the smaller wheel 2500 hp. with two jets.

The machine is shown in Fig. 6 where the oil thrust block can

be seen beyond the bearing to the left of the larger-diameter wheel. The 6.4-ft. wheel has buckets 10 in. in diameter and the 3.67-ft. has buckets 13 in. in diameter.

An interesting feature of the Riva turbine of the Pelton type

on the other end is fulcrumed the floating lever *B*. One end of this floating lever operates the deflector *C* and the other is connected with the governor. The fulcrum itself is connected with jet *K*.

FIG. 6. DUPLEX PELTON WHEEL TURBINE FOR ITALIAN STATE RAILWAYS

is the method of governing speed, or rather the control of the water jet. This is effected in two ways—first by deflection and next by throttling (Fig. 7). In it *A* is the lever working on a fixed fulcrum. To one end of this lever is attached a dashpot *D*;

Suppose the load to be suddenly removed from the turbine and racing to commence. The governor immediately reacts on the floating lever *B* and the deflector comes into action on the water stream. Since resistance is offered in this operation to the turn-

ing of the lever *B* about its fulcrum, the fulcrum itself becomes a moving point about the fulcrum of the lever *A* and the jet *K* begins to close. The arrangement is really an application of the floating lever principle as used in various differential gears to this particular purpose. (*The Engineer*, vol. 128, no. 3332, Nov. 7, 1919. pp. 456-457, 6 figs. in the text, *dA*)

## INTERNAL-COMBUSTION ENGINES

### Why Valves Fail in High-Speed Internal-Combustion Engines

VALVE FAILURES AND VALVE STEELS IN INTERNAL-COMBUSTION ENGINES, Leslie Aitchison. Discussion of the different troubles which arise with valves and steps which should be taken in order to overcome them in the most likely manner, as well as data of tests carried out by the writer, who, during the war, was acting as metallurgist at the British Air Board.

As regards the removal of heat from the inlet valves, it is pointed out that this is done in three ways: First, by conduction down the stem of the valve; second, by direct radiation from the back surface of the head or the neck of the valve; and third, by direct conduction from the face to the valve seat, the third method being the most important.

For proper cooling of the inlet valve two things are essential:

FIG. 7 RIVA SPEED-CONTROLLING ARRANGEMENT FOR PELTON WHEEL TURBINES

First, that the two surfaces shall come accurately together; and second, that the valve shall be closed at the moment of ignition, the second being the more important. The most prolific causes of troubles in valves are those produced by preignition in the cylinder. If the valve is not properly seated at the time of the explosion, there is a rush of hot gases around the valve, taking place at the time when the gases are near to their maximum temperature. The author has examined valves which failed in consequence of preignition and which must have been raised to a temperature of at least 1150 deg. cent. during the process.

Among the other factors which gave trouble is mentioned the work between the guides and the stem of the valves, which is of material importance in rotary engines.

The causes of failure of valves are classified and discussed. Only the most important will be mentioned here.

*Distortion of the head of the valve* may arise from various causes. In one engine it was traced to the fact that the stampings which were used had not been properly heat-treated, and the strains produced by the forging operation had not been removed. When the valve became heated in the running of the engine these strains were released and the valve warped appreciably, sufficiently so to prevent its seating properly. But distortion of the head of a valve may occur even with the proper heat treatment of the forging, and if the valve is so placed that the head is unequally heated this inequality of temperature may have a distorting effect.

Distortion in the head of the valve may further be due to excessive softening of the steel during running, as a result of which the valve is pulled out of shape by hammering against the seat. The causes of the softening are twofold—either the employment of a steel which is not sufficiently strong at high temperatures, or else the utilization of a design in which there is not sufficient metal in the valve head.

*Cracks in the valve face* are a fairly prolific source of trouble. They are usually due to faults of metal, but from whatever cause they may come they are dangerous.

*Excessive wear of the valve foot* is usually found in valves in which a blow of the tappet is delivered directly on to the foot of the valve, or in which the cam acts directly on the valve stem, no cap being fitted to take the blows or the wipe. It is not always easy to provide the proper steel in the foot of the valve to take care of this condition.

*Burning out of the head of the valve* may be due to several causes which may not be entirely attributable to the steel. It is much more nearly true to say that in all cases where burning out occurs, the engine has been running badly. One of the principal causes is the oxidation or scaling of the steel. Cracks in the valve face are also a very prolific source of burning out. If the valve does not sit properly, burning out is almost always a result.

*Breaking of the head or neck* is due to self-hardening. Various cases have been known in which the valve has worked satisfactorily for a certain length of time and then failed by breaking up of the head or the snapping of the neck of the valve. This is found to happen most frequently when starting up an engine which has previously run and then gone cold. Also, the valve which most usually fails in this manner is the one which is manufactured from air-hardening nickel-chromium steel. The valves during the first running have been heated to a temperature greater than, say, 750 deg. cent. and then have been allowed to cool down. As a result of this cooling, the valves have hardened to such a degree that the maximum strength of the steel has reached a figure of possibly 100 tons per sq. in.

This hardening is generally accomplished by the production of a certain amount of brittleness. When the engine is restarted the brittle valve breaks in the head, or else the head falls right off. To obviate this trouble, it is essential that a steel should be chosen which does not harden when cooled in the air from the temperature obtained by the valve during the running of the engine into which it is put.

### IDEAL VALVE STEEL

Steel which is to be used for the manufacture of gasoline-engine valves should possess certain properties and it is difficult to expect all these properties will be found in one and the same steel. These properties are:

- 1 The greatest possible strength at high temperatures
- 2 The highest possible notched-bar value
- 3 The capacity of being forged easily
- 4 The capacity of being manufactured free from cracks, whether these arise in the manufacture of the steel bar or whether they are produced during the forging of the steel.
- 5 The capacity of being heat-treated easily, regularly and reliably
- 6 The least possible tendency to scale, and if scaling does occur the scale should be as adherent as possible.
- 7 The reliability to retain its original physical properties after frequent heatings to high temperatures followed by cooling to normal temperature, also after being heated to an elevated temperature for a considerable length of time
- 8 No liability to harden when cooled in air from the temperature which it will retain when used normally as a valve in an engine
- 9 The capacity of being heat-treated after forging so that it is free from strains liable to produce distortion
- 10 Sufficient hardness to withstand excessive wear in the stem
- 11 The capacity of being hardened at the foot of the stem with considerable ease if necessary

12 The capacity of being machined easily and satisfactorily by ordinary methods.

It does not appear that there is a steel which would possess all of these properties. Table 4 shows the compositions of the various steels which have been used, and there does not seem to be any reason for using such a large variety. In order to evaluate the adaptability of various steels for use in valves, a large number of tests have been carried out, mainly at high temperatures. These tests have been tensile tests chiefly, supplemented by notched-bar tests at high temperatures, and, in some cases, Brinell hardness tests and observation for scaling.

In view of the importance of tungsten steel, Fig. 8 is here reproduced; likewise Fig. 9, showing the resistance to scaling of the various types of steel.

The tests have shown that the principal factor in deciding the properties of a steel at high temperature is its type. By this is meant that all the tungsten steels, for example, have fairly similar properties which make them, as a type, distinct from chromium steels or nickel-chromium steels.

There is a considerable similarity as regards mechanical prop-

FIG. 8 STRENGTH OF TUNGSTEN VALVE STEELS AFTER COOLING FROM HIGH TEMPERATURES

erties at high temperatures between those steels which have a similar constituent.

Among the different steels in any type, variations in composition have a distinct effect upon the mechanical properties at high temperatures. This is particularly true of the high-tungsten and high-chromium steels in which variation in carbon content produces a very marked effect upon the tensile strength or the notched-bar value. This variation is also noticeable in the 3 per cent nickel and 3 per cent chromium steels that is not so marked as in the steels containing a larger proportion of alloying elements. In these steels a variation of 0.2 per cent of carbon will have a greater effect upon the strength than a variation of 5 per cent of tungsten and nearly 7 per cent of chromium.

Tungsten steels with high percentages of carbon (about 0.6 per cent) have the greatest tensile strength at high temperatures. This strength is nearly approached by that of the high-chromium steels containing a high percentage of carbon.

Steels containing a high percentage of chromium with a lower percentage of carbon (such as stainless steel) are distinctly weaker than either high-tungsten steels or the steels containing a similar proportion of chromium with high carbon.

Plain nickel or nickel-chromium steels are quite weak at high temperatures as compared with the other steels. Variations in composition among these steels have apparently very little effect. The influence of vanadium and cobalt appears to be negligible.

As regards scaling, tungsten steels scale comparatively little up to temperatures of about 850 deg. cent., but beyond that they

are liable to scale very considerably. Nickel-chromium steels scale to a greater extent than do the steels of any of the other types, while the high-chromium steels present the greatest resistance to scaling at high temperatures of any of the steels.

The general properties of valve steels in use are next discussed and interesting data are given as to their heat treatment.

The writer recommends the selection of steels from one of the three types: tungsten steel, high-chromium steel and nickel steel,

FIG. 9 COMPARATIVE CURVES OF RESISTANCE TO SCALING OF THE VARIOUS TYPES OF STEEL

eliminating entirely the nickel-chromium steels, and suggests the following allocation for the different steels:

All inlet valves.....3 per cent nickel steel  
 Exhaust valves with a working temperature  
 not higher than 600 deg. cent.....3 per cent nickel steel  
 Exhaust valves with a working temperature  
 between 600 deg. cent. and 760 deg. cent.... high-chromium steel  
 Exhaust valves with a working temperature  
 greater than 760 deg. cent..... tungsten steel

The article contains data of numerous tests on heat treatments which cannot be abstracted for lack of space. (*The Automobile Engineer*, vol. 9, no. 132, Nov. 1919, pp. 401-410, 13 figs., *per al*)

## MACHINE PARTS AND DESIGN (See also Internal-Combustion Engines)

## Present Status of High-Speed Turbine Gearing

HIGH-SPEED TURBINE GEARS, Gerald Stoney. The paper starts with brief historical remarks on the use of high-speed gearing.

The present status of the matter is that gearing is used in all cases for large powers, except in the case of steam turbines driving alternators, where it is found that the satisfactory alternator can be made for speeds suitable for the steam turbine.

As regards types of gearing suitable with steam turbines, rope, chain and belt gearing are all impractical, and the only types used are hydraulic, electric and helical, only the latter being discussed here in detail. The helical gear, among other advantages,

FIG. 10 DIAGRAM OF A PINION OF A HIGH-SPEED TURBINE GEAR WITH INDICATION OF STRESSES

possesses the highest efficiency, between 98 and 99 per cent, and is used especially in marine propulsion on an immense scale.

The design for helical gearing for use with steam turbines is discussed in brief. Tooth speeds up to 120 ft. per sec. are common and have, in many cases, been exceeded. What is exactly the limit of speed is uncertain, but so long as lubrication can be maintained there does not seem to be any reason why the figure

and is one that so far has been only partly worked out.

In England, Messrs. Parsons, who were the pioneers in these gears, resolved not to exceed  $a = 80$  and  $b = 175$ , but as experience was gained  $b$  was increased first to 220 and now to 250.

The distortion of the pinion is next discussed. This is made up of two items—the twist of the pinion due to the torque it transmits, and the bending due to the load on the teeth. In estimating this it can be assumed that the load on the teeth is uniform along the pinion, and it may be further assumed that the effective diameter of the pinion is the pitch diameter.

At any point  $x$  in Fig. 10, the torque  $T$  is:

$$T_x = \frac{pxd}{2} = \frac{2fI}{d} = \frac{\pi f d^3}{16}$$

where  $f$  is the shear stress at the circumference of the pinion and  $I$  is the polar moment of inertia, or  $\frac{\pi d^4}{32}$ . Hence it follows

that  $f = \frac{8px}{\pi d^3}$ . If  $N$  is the modulus of rigidity, which for steel is 12,000,000 lb. per sq. in.,

$$\frac{dv}{dx} = \frac{f}{N} = \frac{dx}{\pi N a^3}$$

$$v = \frac{4p}{\pi N} \frac{x^2}{d}$$

which is a parabola. The twist in the first half of the pinion is:

$$y_1 = \frac{p}{\pi N} \frac{l^2}{d}$$

and the second half:

$$y_2 = \frac{3p}{\pi N} \frac{l^2}{d}$$

FIG. 11 COMBINATION OF GEAR TURBINE WITH A RECIPROCATING ENGINE FOR DRIVING A WIRE ROLLING MILL

given above should not be considerably exceeded. The load on the teeth is determined by the safe limit of bending stress on the tooth and of the pressures at the point of contact, as well as by danger of the oil-film failure. The bending stress can, in general, be ignored. As regards crushing stresses on the material of the tooth, the load per inch run will vary directly as the diameter, or  $p = ad$ , where  $p$  is the load per inch run in pounds,  $d$  the pitch diameter of the pinion in inches and  $a$  a constant. Similarly, the stresses of the oil film will obey some such law as  $p = ba^n$ . The theory of the lubrication of gear teeth is a most difficult one

The alignment of the gears in the gear case is of the greatest importance, as also is the construction of the gear case. In this connection the author discusses the rigid gear-case construction originally introduced by Sir Charles Parsons and the floating-frame type introduced by John H. McAlpine in America.

Several applications of gearing are described and illustrated, such as, for example, a geared turbine driving a cotton mill, and the combination of a geared turbine with a reciprocating engine for driving a wire rolling mill having two shafts running at different speeds (Fig. 11). The compound reciprocating engine runs at

80 r.p.m. and is supplied with saturated steam at 160 lb. pressure, originally exhausting into a central condenser at about 14 in. vacuum giving 2100 hp. By allowing it to exhaust at 16 lb. abs. and leading the steam into a turbine, exhausting into a condenser with 28.8 in. vacuum (barometer 30 in.), the engine gave 1650 i.h.p., and the turbine 1663 i.h.p., or a total of 3313 i.h.p., an increase of 58 per cent in power with no increase in steam used, giving an increased economy of 36.6 per cent. The exhaust turbine runs at 3700 r.p.m., and the geared shafts at 500 r.p.m. and 250 r.p.m. The difficulty of the uneven turning moment of the reciprocating engine and the even turning moment of the steam turbine straining the gear is met by the flexibility of the rope drive. For starting up, the reciprocating engine can be exhausted to atmosphere.

It may be noted that if the power supplied to each low-speed shaft is equal, there will be no bending of the pinion, and the only distortion will be that due to twist. (Paper before the Manchester Association of Engineers, Nov. 22, 1919, reprinted in *Engineering*, vol. 108, Nov. 28, 1919, pp. 729-733, 14 figs., dg)

## POWER PLANTS

### How Large Can Steam Turbines and Turbo-Generators Be Made Today?

**PRESENT LIMITS OF SPEED AND POWER OF SINGLE-SHAFT STEAM TURBINES AND TURBO-GENERATORS.** A symposium of three papers. The first, by Eskil Berg, starts by showing that the limit of a single-unit turbo-generator does not lie in the generator, but is confined to the steam turbine, and that the limiting feature of the latter is the last wheel. The paper is based mainly on the work done by the General Electric Company.

(Questions of design of the large turbines and of the conditions limiting the size are discussed.)

Efficient action of the blades in large-size turbines operating with high vacuum can be accomplished only by using the bucket speed that bears a proper relation to the steam velocity, which means that to get the largest capacity not only long buckets must be used, but they must be moved at a very high speed. On the other hand, to obtain good bucket action the buckets should not be more than about one-quarter as long as the pitch diameter of the wheel.

The use of a high-steam speed in the last stage naturally implies that a relatively large proportion of the total steam energy must be utilized there, and such concentration of work into a single stage has its disadvantages, even if the best relations of velocities is maintained.

Since such a stage is doing a large amount of work, it is naturally less efficient than a stage of similar character doing less work.

In this way the last wheel of the turbine becomes one of the limiting features of the overall dimensions. Energy and efficiency curves (Fig. 12) of the last stage are given which show that at the most efficient point this stage absorbs 11.5 per cent of the total adiabatic available energy, and that the wheel efficiency is 66.25 per cent. But this is for an output of 21,000 kw., and in the same turbine when the load increases to 36,000 kw. the energy in the last stage is 20.9 per cent of the total energy and the wheel efficiency goes down to 54.2 per cent.

The conclusion which the author comes to is that for a given speed there is one particular size of turbine which can be designed to be most economical as to steam consumption, weight, space and price per kilowatt. Even if a size smaller than this is required, it would, in many instances, pay for the central station to install a larger unit, even though it would have to run at reduced load for some time before the station load increased sufficiently to utilize its full capacity. (*Proceedings of the American Institute of Electrical Engineers*, vol. 38, no. 11, Nov. 1919, pp. 1223-1231, 6 figs., g)

In the second paper, F. D. Newbury discusses the conditions determining the size of a turbine and conditions limiting it.

In the opinion of the writer, maximum output at any speed

when reduced to the simplest terms is attained when slot space is provided for the maximum possible ampere-turns (in either stator or rotor), and core cross-section is provided for the maximum possible flux. These conditions require the most effective rotor diameter and the maximum rotor and stator core length.

The most effective rotor diameter for a given speed is not necessarily the largest diameter, and to obtain maximum output at a given speed the rotor proportions must be chosen properly to balance mechanical stresses, rotor ampere-turns and flux.

The electrical factors in generator design are discussed by the writer, who believes, among other things, that a fundamental difficulty in setting down definite limiting outputs is the difficulty in arbitrarily setting limiting stresses.

On the other hand, limit of length of the rotor and stator cores is determined mainly by such considerations as cooling-air requirements, bearing proportions, by limits to weight imposed by transportation facilities and the ability to secure forgings of necessary diameter and weight.

To give an idea of the character of these limitations, it may be stated that, for example, transportation facilities may impose a limit to size in the case of 6- and 8-pole 60-cycle generators. From the special nature of their design and the special skill and equipment required for winding and assembling, rotors should be completed at the builder's factory and shipped as a unit. The

FIG. 12 ENERGY AND EFFICIENCY CURVES (LAST STAGE) OF A LARGE TURBINE

weight of the complete rotor of a 4-pole 1800-r.p.m. generator of 40,000-kva. capacity will be roughly 90,000 lb. This can be transported without difficulty, but the largest possible 12,000-r.p.m. rotor would weigh more than 200,000 lb. and would require rolling stock and trackage in some cases not now available.

Another general limitation to output of larger-diameter rotors is that imposed by the forging facilities of the country. At the present time it is not possible to obtain forgings of suitable physical characteristics weighing more than 50 or 60 tons nor much larger than 50 in. This limits the rotor made from a single forging to an output of, roughly, 50,000 kva. at 1500 r.p.m. By adopting the rotor construction involving 2-in. or 3-in. plates and upset flanged shaft ends, the limiting diameter may be increased sufficiently for the largest 1500- and 1200-r.p.m. outputs shown in Fig. 13.

This figure shows in curve form limiting generator capacities at various speeds. At 1500 r.p.m. and higher the capacity is determined by the rotor and is inversely proportional to the r.p.m. squared. At lower speeds the capacity is limited by the stator and falls somewhat below the corresponding rotor limiting capacity, as indicated by the dotted extension of the rotor curve. The curve is an indication of the present boundaries based on existing commercial materials and current stresses and bearing proportions. In fact, the capacities shown by it are somewhat in advance of accomplished results.

The writer claims that mechanical forces due to short-circuit and damage caused by armature-winding failures are no greater in the very large generators, indicated by the above figure, than the present-day 20,000- and 30,000-kva. unit.

No opinion is expressed as to the wisdom of installing very large single-shaft units. If operating engineers desire units of 50,000 to 100,000 kva., there is no question but that such generators can be conservatively designed and constructed. *Proceedings of the American Institute of Electrical Engineers*, vol. 38, no. 11, Nov. 1919, pp. 1233-1242, g)

The paper by J. F. Johnson is restricted to a discussion of some of the factors which influence limits as applying particularly to turbines of the reactionary type. The author expresses the opinion that with the employment of high vacua the limit of power is determined largely by the area obtainable through the last stage, for the final expansion and passage of the steam prior to its entering the condenser.

The significance of this is shown by the fact that whereas a pound of steam when entering the first stage has a volume of less than  $2\frac{1}{2}$  cu. ft., when passing through the last stage it has a volume of approximately 395 cu. ft. if expanded to 28.5 in. vacuum, and 555 cu. ft. if expanded to 29 in., the ratio in the latter case being 1 to 234.

Because of this, in any discussion of limits of power it is neces-

FIG. 13 LIMITING GENERATING CAPACITIES IN LARGE UNITS AT VARIOUS SPEEDS.

sary to assume conditions of pressure and superheat of the steam entering the turbine, the vacuum to which the steam is to be expanded in the blading and the efficiency of change of steam flow per unit of power.

The limiting factors are divided into three classes by the author: (1) Theoretical, including limiting steam velocities and effect on efficiency of velocity remaining in steam after leaving the last stage, and the area through the blades as affected by blade angle; (2) Physical, including methods of construction, materials, stresses, factor and safety against rupture, reliability factor, and limitations of transportation facilities; (3) Economical, including limits beyond which it may be physically possible but economically inadvisable to go, such as effect of size of structure or of character of materials employed on costs and time required to make inspection and repairs. The paper is largely based on the practice of the Westinghouse Company.

As regards theoretical limits with materials of infinite strength and rigidity, it would have been possible to build units of infinite capacity, but for a given diameter and blade height the capacity is limited by chosen maximum values of steam speed through the blades, in order to keep the energy available in the steam discharged to the condenser within permissible limits.

Throughout the entire turbine, with the exception of the last few stages, steam speeds only about 25 per cent in excess of the corresponding blade speeds are employed in order to secure maximum efficiency. In the latter stages, however, the volumes become so great that steam speeds are increased sometimes approximately 100 per cent in excess of the blade speed, in order to effect a compromise between maximum theoretical efficiency and physical dimensions.

The question of blade angle is discussed next.

As regards the physical limits, the chief ones limiting turbine

capacity are the physical characteristics of the material employed and the chosen limits to which these materials may be safely stressed.

Of course, the design of the rotor materially affects the stresses involved, but if the rotor design can be so modified as always to keep the stresses within necessary limits, then the stresses at the base of the limits or in blade fastenings determine the maximum capacity obtainable with a given speed.

There exist two interesting relations between the stress at the base of blades, steam-passage area through the blades, and rotative speed. For any given rotative speed and blade angle the steam capacity or steam area through the blades is directly proportional to the stress at the base of the blades, regardless of the diameter and blade height selected. This stress can only be modified by unevenly varying the cross-sectional area of the blades, such, for example, as thickening the blade near the base. Also for any given stress the area through the blades will vary inversely as the square of the speed, i.e., if at a speed of 1800 r.p.m. a given stress and area are obtained, then at 900 r.p.m. the area will be increased four times if the stress is kept constant.

In other words, as the writer shows in the original article, the area and stress are each equal to a constant times the product of mean diameter and blade height, and when the stress is constant this product varies inversely as the square of the revolutions per minute. The ratio of blade height to rotor diameter is therefore not a factor in determining physical limit of capacity, but only in determining efficiency cost and, to some extent, reliability of the turbine.

Increased capacity without decrease of rotative speed or increase in stresses may be obtained by employing multiple low-pressure stages, and the author gives a curve showing the limits of capacity of steam turbine with double-flow low-pressure stages.

In discussing the economic limits of turbines of large capacity, consideration is given to the fact that as yet such units are not required in sufficient quantity to warrant equipping and operating shops for their exclusive manufacture, and that they must be produced largely by the same processes and equipment as are used for smaller sizes which are built in greater quantities.

As the sizes become larger, a greater proportion of special equipment and processes becomes necessary, resulting in increased rates of cost unless accompanied by very material increase in production of quantity. Under present conditions this economic limit of capacity agrees closely with the physical limit of 1500 r.p.m. units.

Another factor tending to limit capacity of single units is the generating capacity loss resulting from suspension of service for inspection or repairs. For example, if a 30,000-kw. unit must be kept out of service ten days for a certain inspection or repair, a 60,000-kw. unit would have to be kept out probably fourteen days for a similar purpose because of the greater time required to handle the larger structure. Therefore, if two 30,000-kw. units were used and each held out of service ten days, the outage loss would be only five-sevenths as great as if a single 60,000-kw. unit were kept out fourteen days. (*Proceedings of the American Institute of Electrical Engineers*, vol. 38, no. 11, Nov. 1919, pp. 1243-1253, 6 figs., g)

### Standardization in Power Piping

POWER PIPING, J. Roy Tanner and Geo. J. Stuart. A paper discussing the subjects of piping systems, their design, selection of materials, and details of construction.

The steam pressures carried have gradually increased until the present extra heavy material used for high-pressure steam is designed for 250 lb. working pressure, and the tendency is still upward. Material designed for 350 lb. and superheat is actually in use but has not yet had wide enough application to be reduced to standard practice.

The steam turbine has changed practice by bringing superheated steam from occasional into extensive use. This made it necessary to find substitutes for cast iron and bronze in fittings.

The former was replaced by cast steel and the latter, to a great extent, by Monel metal.

The importance of standardization as a factor in the industrial position of this country today is nowhere better illustrated than in this industry under discussion. A few years ago each manufacturer had his own standard for the dimensions of flanges, fittings, and drilling templets. This compelled the large users of piping, such as steel mills, to adopt something which was very likely to be original. Also, about the first thing an engineer did after putting up his sign, was to calculate and design his own piping standard. There was a tremendous amount of brain power consumed which can now be diverted to other purposes. The effect of this confusion was that manufacturing in all that the word implies was impossible because changes of flange sizes or center to face had to be made at frequent intervals. This condition prevailed long after The American Society of Mechanical Engineers, in 1894, adopted, after conferring with the Master Steam and Hot-Water Fitters and some of the manufacturers, a standard flange templet which subsequently became the "A. S. M. E. Standard" used for lower pressures, along with the "Manufacturers' Standard" for extra heavy material, in 1901, and it was several years after this before the flange situation became clarified.

Some time after 1910 a group of manufacturers of valves and fittings formed an organization called the Committee of Manufacturers on Standardization of Valves and Fittings, and began the work of designing a completely standardized line of fittings, including center to face, and shell thickness. This work was completed and published and about a year later revised to meet the views of The American Society of Mechanical Engineers regarding the bolting of extra heavy flanges larger than 12 in. This revision was accepted at a conference in Washington by representatives of the United States Government. The American Society of Mechanical Engineers, the Master Steam and Hot-Water Fitters, and the Manufacturers' Committee. The American Society of Mechanical Engineers adopted the report of its Committee—compiled under the direction of the late Mr. H. G. Stott—and thus made effective the American Standard for Pipe Flanges, Fittings and Their Bolting, to become effective January 1, 1914. The report of this Committee was a masterpiece of complete analysis.

The American Standard consisted of specifications for "Standard" material up to 125 lb. pressure and "Extra Heavy" material up to 250 lb. pressure.

The American Society of Mechanical Engineers and the Manufacturers subsequently collaborated in standardizing hydraulic flanges up to 3000 lb. pressure, culminating in the adoption of a report in December, 1918.

Economy demanded the use of a lighter design than that specified for 125 lb., for use on low-pressure water, condenser service, etc., and The American Society of Mechanical Engineers has made a recommendation for lighter shells and smaller bolts than the American 125-lb. standard, and flanges of the same diameter, thickness, and bolt spacing. The Manufacturers' Committee, however, is considering the advisability of using a thinner flange for this service, owing to the foundry difficulties attending such a great change in section, and may request The American Society of Mechanical Engineers to reconsider this point.

Some work had been done by the Manufacturers' Committee to determine the feasibility of standardizing valve dimensions from center to face, but with no results. In the fall of 1918, when the Emergency Fleet Corporation was struggling with the problem of a design for the piping of fabricated ships, the standardizing engineer for the Emergency Fleet Corporation, Mr. John A. Stevens, who played a large part in formulating the Boiler Code of The American Society of Mechanical Engineers, attacked the problem of interchangeable dimensions for the valves to be used by the fleet, calling to Philadelphia engineering representatives of all the large valve manufacturers and, had it not been for the armistice, the fleet would probably by now have had a standard center-to-face dimension for every valve to be used by them on shipboard. It is therefore not impossible that at some future date we may even have interchangeable face-to-face dimensions of valves.

A large amount of standardization work has been done by the Power Piping Society, an organization of fabricators and erectors. The "Standard Specifications for Power Piping" adopted by the society in 1915 was the result of the experiences of a group of men who had installed a considerable part of the power piping in this country, and can therefore be accepted as safe modern practice.

Thus out of chaos has come some degree of order, for the benefit of the use of pipe, valves, and fittings. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 35, no. 7, Oct. 1919, pp. 311-332 [original paper] and 333-347 [discussion], g)

**COXON AUTOMATIC STOP VALVES.** Description of a series of devices of British manufacture designed to automatically shut off steam in the event of a burst in the steam main or a similar ac-

FIGS. 14 AND 15 COXON AUTOMATIC INSULATING VALVE FOR STEAM HEADERS

cident to the apparatus to which it is supplied. The valves described and illustrated comprise a boiler junction valve, a combination safety valve and stop valve and an insulating valve for steam headers. This latter is shown in Figs. 14 and 15. The casing contains two similar valves, closing in opposite directions. The lower one is forced to its seat by means of the hand wheel and screw, and acts as an ordinary stop valve when closed in this

way. The valve spindle, however, is separate from the screw, and the valve can thus close independently of the hand wheel. The upper valve has no screw, and the spindle slides freely in its gland. When in use, both valves are normally held open by the steam pressure, but should the main burst on either side, the corresponding valve closes automatically and prevents steam flowing to the burst part. No by-pass is required to open the valve, because when the lower valve is shut it lifts the upper automatic valve slightly from its seat. When steam is admitted to the main, the upper valve also opens as soon as permitted by the operation of the hand wheel.

A feature of the valves described is that they have no springs and are so arranged that they can be readily tested at any time. (*Engineering*, vol. 108, no. 2809, Oct. 31, 1919, pp. 581-582, 9 figs., d)

WHAT SHOULD BE THE MAXIMUM LENGTH OF A LONGITUDINAL JOINT, C. E. Stromeyer. Attention is called to this article, the author of which is Chief Engineer of the Manchester Steam Users' Association for the Prevention of Boiler Explosions, and to an editorial on p. 624 of the same issue of *Power*. The article and the editorial are here abstracted together.

The writer of the article draws attention to the differences of engineering views on the two sides of the Atlantic. He claims that in England boilers have been made so safe that fatal boiler explosions rarely reach a dozen per year. He was shocked when on a recent occasion he heard an address by an American engineer who claimed to be qualified to speak about the practical working of boilers because he had been present at a dozen boiler explosions. Such an exciting experience is quite impossible in England.

The writer thinks, however, that there must be other causes than the use of long longitudinal seams to account for these numerous explosions and if these other causes be removed the question of length of joints will sink into insignificance.

The writer employed special strain indicators to measure the strains in the solid plates of boilers on either end of lap joints and also in the solid plates above and below the single-butt-strap joint of the hulls of iron ships, which construction was customary some thirty years ago. His observations showed that the strains in the solid plates close to the ends of lap joints were eight times greater than those in the solid plates away from the joints. Assuming that these joints had only 70 per cent of the strength of the solid plates, it is evident that the plates that adjoin lap joints are stressed about five times more severely than the joints themselves. These observations had been confirmed by unpublished experiments made in 1874 by the Manchester Steam Users' Association on a full-sized boiler whose solid plates ruptured under hydraulic pressure when the seams gave way.

The conclusion that is to be drawn from these two sets of experiments is that the breaking of joints is a source of weakness, that the longer we make the longitudinal joint for boilers the better. The author qualifies this statement, however, saying that it is intended to apply only to steels made by the acid open-hearth process. The Manchester Steam Users' Association refuses to sanction the use of basic steel in boilers.

As regards the experience of the Manchester Steam Users' Association, it is stated that since its foundation in 1854 it has issued over half a million certificates of safety and up to the time of the war it had had no accident entailing loss of life.

The editorial commenting on this article, asks:

"Why the Massachusetts Boiler Board considers both lap and strap joints dangerous in lengths exceeding 12 ft., while the Boiler Code Committee of the A. S. M. E. is apprehensive for lap joints only?"

"Why the Board of Boiler Rules prohibits these joints on horizontal return-tubular, vertical-tubular, or locomotive-type boilers, and the A. S. M. E. only on horizontal return-tubular boiler?"

"If they are dangerous in the shell of a locomotive-type boiler, why they are not equally dangerous in the drums of water-tube boilers?"

The editorial in *Power* also calls attention to the fact that both

the Massachusetts Board and the A. S. M. E. Committee agree that the long joint is bad and should be avoided, while Mr. Stromeyer asserts that he is strongly in favor of long seams and prefers them to short ones, even if the plates are rolled parallel to the seams. (*Power*, vol. 50, no. 17, Oct. 21, 1919, published Dec. 1, 1919, pp. 626-627 (original article), and 624 (editorial comment) *gp4*)

EXPLOSION OF LAP-SEAM BOILER. Description of the explosion of a boiler as the result of a lap-seam crack which occurred at the boiler plant of the Sisters of St. Francis of Assisi at St. Francis, Wis. The boiler was 60 in. in diameter, 40 ft. long, and constructed of 3/8-in. plate of flange steel and was built in 1904. There were two sheets of the shell plates, each sheet forming a complete ring with the longitudinal seam in the usual place, above the water line.

The longitudinal seams were of the double-riveted lap-joint type, there being two rows of 7/8-in. rivets driven in 15 16-in. holes, with a rivet spacing of 3 3/4 in. The spring-loaded safety valve was set to blow at 95 lb. pressure. Information available shows that the boiler was clean and had received good attention in other ways. After the accident the safety valve was found to be perfectly free and unobstructed.

Examination of the exploded boiler developed the fact that the front course of the shell plate had failed from the head seam to the girth seam, a distance of 6 ft. 9 in. along the rivet holes of the double-riveted lap seam. The crack probably started at a point about 5 ft. from the front head where the plate was not homogeneous and gradually extended to the front-head seam, working deeper into the sheet until separation occurred. (*Power*, vol. 50, no. 17, Oct. 21, 1919 [published Dec. 1], pp. 604-605, 2 figs., d)

PLACING A NEW TURBINE IN SERVICE, Roger Taylor, Mem. Am. Soc. M. E. An article of a strictly mathematical nature not suitable for abstracting. Attention is called to it because it presents

FIG. 16 HORWICH LOCOMOTIVE SUPERHEATER

data as to procedure followed in putting a steam turbine into service not easily found in print elsewhere. Such features as leveling, alignment, checking bucket clearance, adjustment of thrust and step bearings, valve setting and governor adjustments are considered. The article is the first of a series. (*Power*, vol. 50, no. 16, Nov. 22, 1919, pp. 578-582, 9 figs., p)

## RAILROAD ENGINEERING

"HORWICH SUPERHEATER FOR LOCOMOTIVES. A number of heavy 0-8-0-type locomotives at present being constructed at the Horwich Works of the Lancashire & Yorkshire Railway are fitted with the new type of superheaters, shown in Fig. 16.

In this superheater there are three separate headers, one at the top and two at the bottom of the smokebox, the latter being in direct communication with the cylinder steam chests. Saturated steam from the boilers enters the top header and branches right and left from a central chamber. Steam passes along small pipes

enclosed in large flue pipes in the ordinary way, traversing the length of the boiler toward the firebox, returning toward the smokebox, then again toward the firebox and finally to the lower headers in the smokebox, thence to the smoke chest and cylinders. The large flue tubes are arranged in two vertical rows on each side, and in the particular boiler illustrated there are twenty elements. This arrangement gives a short direct connection between the lower headers and the cylinders for the passage of steam.

Owing to the fact that the saturated- and superheated-steam receptacles are separated from one another and the usual smokebox steam pipes dispensed with, any loss of superheat occurring during the passage of steam from the outlet ends of the superheater headers to the steam chests is reduced to a minimum.

It is also claimed that the parts are readily accessible and cleaning facilitated. (*The Railway Gazette*, vol. 31, no. 18, Oct. 31, 1919, pp. 556-557, 3 figs., d)

The low-pressure end has a header made of 16-in. pipe and carrying a 6-in. dry pipe (Fig. 17), the dry pipe being welded at each end to a plate, which, in its turn, is welded to the header. On the inside opposite the gas-admission side the dry pipe has a slit 2 in. wide for its entire length through which the gas passes into the dry pipe and thence to the suction pipe. To the bottom of the dry pipe is riveted a curved baffle plate which changes the direction of the gas flow from the coolers so as to throw out some of the entrained liquid. Both dry pipe and header are given a slight pitch toward the dead end, where liquid may drain into the header from the dry pipe and from the header into the coolers. The circular plate in the outlet end of the header has an opening of segment shape into the header, the opening being immediately above that into which the dry pipe is welded and so situated as to pass gas collecting at the top of the header to the suction pipe.

The conditions created by this and other means are such that

FIG. 17 COMPRESSOR OF THE T-WHARF PLANT OF THE QUINCY MARKET COLD STORAGE COMPANY, BOSTON, MASS.

## REFRIGERATING ENGINEERING

### Improved Compressor at Quincy Market, Boston

QUINCY MARKET COLD-STORAGE PLANT at BOSTON, CHAS. H. BOWLEY. Description of the so-called T-wharf plant of the Quincy Market Cold Storage and Warehouse Company. The station is of 500 tons rated capacity in one compound high-speed leather-valve ammonia compressor driven by a 600-hp. synchronous motor. The most remarkable part of it is this compressor.

Essentially it is of the standard Laidlaw type, but has a special arrangement of gas connections and gas intercooler.

The compressor has a 24-in. stroke, a low-pressure cylinder of 27 in. bore and a high-pressure cylinder of 15-in. bore. The low-pressure cylinder has 12 valves each with a free opening area of 9 sq. in., and the high-pressure cylinder six valves of the same area.

liability to slop over is remote under normal conditions, and, in any event, a slopover comes gradually and not in one smashing flow. There is a condition which tends to produce a slopover when the rate of feeding liquid to the brine coolers is suddenly and markedly reduced. The expansion-line nozzle inside the cooler projects the liquid upward at an angle on a line with the top far end of the cooler. Feeding may be so rapid that the liquid in the cooler will pile up at this end and thus leave more disengaging volume between liquid level and cooler top at the gas outlet end than existed before increasing the rate of liquid flow.

Another interesting feature of the compressor is the intercooler. The cooling medium is liquid ammonia taken direct from the liquid receiver. The principle of the intercooler is identical with that of the open feedwater heater, and the intercooler is provided with trays and baffles just as is the open heater. Liquid direct from the main liquid receiver is run through the intercooler, and what is not evaporated goes to the brine coolers. The gain is, of

course, twofold: First, the gas is cooled, reducing the volume to be handled by the high-pressure cylinder; second, liquid in cooling by its own expansion uses up, say, 15 per cent of its cooling effect in cooling itself. Compared with its condition in the liquid receiver, this liquid passed through the intercooler has already lost this in a most useful way—the liquid as well as the gas has benefited by the heat exchange in the intercooler. As the intercooler pressure is 60 lb. and that in the brine coolers 5 lb., the liquid is trapped just before it reaches the coolers. It is convenient to use the last or No. 8 condenser as an intercooler, taking the gas before it goes to the liquid-gas intercooler.

The designer has cleverly obviated the use of a concrete crib at the harbor end of the suction pipe. This suction is 10 in. in diameter and at the harbor connects with a 10 x 8 x 8-in. Y. At each 8-in. outlet of the Y is a gate valve, a short nipple on the end of which is fitted with 12 ft. of 8-in. flexible rubber hose. On the end of the hose is a strainer made of 12-in. pipe, slotted to give capacity considerably greater than that of the 10-in. suction.

Several other interesting features at the new plant are discussed and illustrated in the original article. (*Power*, vol. 50, no. 18, Oct. 28-Nov. 4, 1919, pp. 638-644, 9 figs., dA)

## STANDARDS

THE MASS OF THE LITER OF AIR AND GAS MIXTURES. Critical abstract of a memoir on The Mass of the Liter of Air, published by Prof. A. Leduc in vol. 16 of the *Travaux et Mémoires du Bureau International des Poids et Mesures*.

Objections are made to the use of air as a standard of measurement. When this is done the composition and density of the air are tacitly assumed to be constant, the data having been reduced to normal temperature and atmospheric pressure. But the air density is not constant and the buoyancy is sufficiently affected by a barometric change of a few millimeters to upset balance established even between lumps of quartz and of platinum, each weighing one kilogram.

While the air density does not fluctuate widely, under ordinary conditions, such deviation as takes place is well within the limits of precise measurement.

The air measurements are also affected by the composition of the air. Thus, oxygen, being heavier than nitrogen, becomes concentrated in the lower atmosphere, this tendency, however, being counteracted by winds and convection currents. Further, air in laboratories may be seriously contaminated by water vapor and carbon dioxide, which are removed before analyzing the air but usually disregarded in density determinations.

There is another objection to the use of a mixed gas like air as a standard.

Dalton's law was formulated in ignorance of the fact that nearly all gases are more compressible than they should be according to the law of Boyle and Mariotte. Leduc's own experiments would lead to the following conclusions:

If we have equal volumes of two gases, A and B, at equal pressure P and allow the gases to mix, A will not, in the doubled volume, be at the pressure  $P/2$ , but at the pressure  $P/2 + \epsilon$ , because the gas is more compressible than it should be; similarly B will be at a pressure  $P/2 + \epsilon$ , and the pressure of the gas mixture will be  $P + \epsilon + \epsilon$ ; but this ( $\epsilon + \epsilon$ ) is not a constant and depends upon the nature of the gases. In one series of experiments to demonstrate this Leduc and Sacerdote connected two flasks of equal volumes, charged with various gases, by a three-way cock, and hastened the mixing of the two gases by cooling and heating the one or the other vessel and by shaking. Diffusion was very slow; sometimes it took days and weeks to obtain a mixture of constant composition (as shown by analysis) and pressure. In the case of two substances like CO<sub>2</sub> and N<sub>2</sub>O (which physically differ little) there was no distinct increase in pressure; in the case of two gases like H<sub>2</sub> and SO<sub>2</sub>, physically dissimilar, there was a pressure rise of 3 mm. It is clear, therefore, that the nature of the gases has to be considered. What is less clear—from the brief account of the memoir, at any rate—is whether all possible chemical and other disturbing effects can be allowed

for in such experiments, and whether Leduc's version of Dalton's law meets the required conditions, namely, that the volume occupied by a mixture of gases is equal to the sum of the volumes occupied by each of the constituent gases at the same temperature and at the pressure of the mixture. As regards the atmospheric mixture of nitrogen and oxygen, the  $\epsilon$  may practically be disregarded, Leduc finds; but the fact could not be presumed.

In the experiments made to determine the mass of the liter of air it was found that the rare gases, excepting argon, and hydrogen would only affect the 5th decimal of the air density, which is uncertain anyhow and may hence be neglected.

Samples of air taken in different parts of France and in Africa at various altitudes show that the oxygen proportion by weight varied between 0.2305 and 0.2325 and further the oxygen proportion was lower than the average in the north of France at sea level, which, it is suggested might account for the slightly lower oxygen values of Rayleigh.

The final result is that the liter of air at 0 deg. cent. and 760 mm. barometer weighs 1.2928 grams when  $g = 980.665$ . Under one megabar, taking the density of mercury as 13.5951 and  $g$  as 980.97, the mass of the liter of air would be 1.2759 grams. (*Engineering*, vol. 108, no. 2809, Oct. 31, 1919, p. 569, tA).

## STEAM ENGINEERING (See also Power Plants and Railroad Engineering)

HEAT TRANSMISSION IN BOILER FLUES, Michael Longridge. In carrying out tests on a new type of boiler some years ago the author tried to determine whether heat transmission in boiler flues is proportional to the product of the density and speed of gas when the water circulation is well maintained. While the tests were not exhaustive enough to answer this question in a positive manner, enough data were secured to create a doubt as to its truth.

If the transmission per square foot of air per degree temperature difference were strictly proportional to the product of the density and speed of the gas the values of  $H/\Delta\varrho u$  (where  $H$  is the average B.t.u. transmitted per sq. ft. of air;  $\Delta$  mean temperature difference between gas and steam or water;  $\varrho$  mean density and  $u$  mean velocity) would be constant in each case though the constant values might be different for the plug flue for the evaporator and for the economizer.

Actual test data show that in the case of the economizer the values are approximately constant and therefore approximately in accordance with the law  $H/\Delta\varrho u = \text{constant}$ .

In the case of the evaporator the variation is greater, and for this there are two reasons: First, greater uncertainty as to temperatures and radiation losses; second, the fact that owing to some of the tubes being bent the gas current was not evenly distributed over the cross-section of the flue.

In the case of the plug flue the variation is considerable, but here it must be remembered that the plug was quite hot at one end and more than red hot at the other end, and therefore the radiation from it was very great. As a result of this the heat absorbed by the flue plate was much greater than if the plate had received heat from contact with the hot gases only.

It appears, therefore, that the general law, namely, that heat transmission in boiler flues is proportional to the product of the density and speed of gas when the water circulation is well maintained, is well supported. (Abstract from an unpublished copy of a report made by the author who was Chief Engineer of the British Engine Boiler and Electrical Insurance Company, Ltd., of Manchester, England, on December 31, 1909. While not of recent date the report is of interest and this is its first publication, a copy having been secured through the courtesy of Daniel Adamson, Mem. Am. Soc. M. E.; g)

## CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

munications should be addressed to the Editor.

## Our New President and New Past-President

Major Fred J. Miller, the new President of The American Society of Mechanical Engineers, brings to this important position the fruits of many years of wide experience in large affairs. In the introduction of the President-elect on the evening of the President's Reception at the Annual Meeting, it was stated that "for 20 years he was a journalist, since which time he has been engaged in the business of factory management, an expert on factory management. He served for five years on the Council of this Society, and for four years as Trustee of the United Engineering Society. His work as Trustee of the United Engineering Society had to do with the reorganization of its finances and other features, but principally with the work of reorganization. During the past year he has had made a survey of the machinery—the office machinery—of this Society, and he has advised with regard to the development of MECHANICAL ENGINEERING, the Journal of the Society. He had also rendered very distinguished service in the cause of his country during the war."

The position of President of the A.S.M.E. has come to be in reality a position demanding a large amount of time and personal attention, not only to Society affairs almost overwhelming in amount, but to public matters of broad scope in which the interests of engineers are involved. The Society is to be congratulated on having for its leader during the coming year one whose experience and intimate acquaintance with the Society so well qualify him to conduct affairs which need the sound judgment of an able executive and officer. An account of Major Miller's life will be found in Section Two of this number.

For the work of Dean M. E. Cooley, the retiring President, the utmost gratitude is felt by all the members of the Society and all who have been acquainted with his constructive genius. Making the trip from Ann Arbor, Mich., to Society headquarters each month, and sometimes oftener, and giving practically half his time to his presidential duties, he has displayed a devotion to the cause of the profession for which the Council and his fellow-members in the Society have the fullest appreciation. His grasp of Society activities is shown in his presidential address printed elsewhere in this number. The manner in which he has handled

the many problems that have arisen, with combined forcefulness and geniality, has been most happy and effective and has won the admiration of his associates and his many friends.

## Engineering Index Issued in a New Form

The Engineering Index has now been conducted by The American Society of Mechanical Engineers for a period of one year, and as a result of this experience a change has been made in the arrangement of the items comprising the Index, beginning with this number of MECHANICAL ENGINEERING. Heretofore the classified system has been employed whereby the items were grouped under several broad headings, such as Mechanical, Electrical, Civil and Mining Engineering, Marine and Railroad Engineering, Organization and Management, General Science, etc.

During the year suggestions have been solicited from the membership for the improvement of the Index, with the result that practically all of the criticisms or suggestions have pointed in the direction of adopting a simple dictionary arrangement of the items rather than the classified arrangement. This led the Publications and Papers Committee of the Society to make an investigation and secure the opinions of engineers, librarians, and others who have given attention to the matter, which have confirmed the opinions previously received to the effect that the alphabetical arrangement, all things considered, is to be preferred.

To turn from a classified system to an alphabetical one presents many problems, to solve which requires time and effort. Undoubtedly many suggestions can be made for the further improvement of the Index as it appears in the current issue of this Journal, and it is hoped that those who consult the Index will feel free to communicate with the editor with regard to any deficiencies and give, if possible, constructive suggestions for future improvement.

## Engineering Societies Employment Bureau Completes a Successful Year

During the past year the four Founder Societies have jointly maintained in the Engineering Societies Building an Employment Bureau, open to all engineers, and especially extending its aid to discharged engineer officers and men. During the year the Bureau has interviewed over 20,000 men and has handled nearly the same number of applications. At present there are approximately 5000 men registered, many of whom, however, are already employed and have entered their names in order to advance themselves should opportunity offer. About 2500 positions are now available. Here is an opportunity for effective cooperation. Business men and engineers who are seeking new blood for their organizations can without question profit by communicating with the manager of the Bureau, Mr. W. V. Brown, who should be addressed at 29 West 39th Street, New York, N. Y.

It should not be inferred that because of the smaller number of positions available men are not in demand. On the contrary, good men are constantly in demand and many of the positions now available call for engineers of particular qualifications. Those seeking engineering positions will therefore find it advantageous to enlist the aid of the Bureau.

## National Public Works Department Association Holds Conference in Washington

The National Public Works Department Association, which grew out of a conference called by Engineering Council, and held last April in Chicago, will meet at the Willard Hotel in Washington, D. C., on January 13 and 14. The purpose of the conference is to discuss the Jones-Reavis bill, which is now being considered by Congress, and which proposes far-reaching changes in the organization of the Federal Government. This bill, to which reference has frequently been made in these

columns, proposes to create a Department of Public Works to replace the Department of the Interior. It is the primary object of the bill to assemble under one head all of the engineering activities of the Government and to place under the jurisdiction of existing appropriate departments such activities as are of a non-engineering character. The various details of the bill will be found in the August issue of MECHANICAL ENGINEERING (page 709).

The Tuesday session of the conference will be given over to a discussion of various committee reports and of the Jones-Reavis bill itself. The practical results achieved by the public works departments of several of the states will also be discussed. It is the hope of the National Public Works Department Association that every engineering organization in the country be represented in this conference, for the bill is one not alone of interest to engineers, but to the country at large.

## Annual Volume of Engineering Index to Be Alphabetically Arranged

The Engineering Index, which has been a monthly feature of MECHANICAL ENGINEERING during the past year, will later be issued in the form of an annual volume, according to the practice followed by the former publishers of the Index for many years past.

To meet the demand for an alphabetically arranged index, however, which a consensus of opinion clearly indicates is the most convenient form for reference purposes, the items have been entirely regrouped according to this plan, instead of following the classified arrangement of the Index as it has appeared in MECHANICAL ENGINEERING and in the previous annual volumes. By introducing many cross-references the engineer will be able to find under one heading all the references to any one subject.

For instance, under the new plan references to screw-thread gages will be found under the heading GAGES, *Screw-Thread*, instead of MECHANICAL ENGINEERING, GAGES, *Screw-Thread*. In other words, one will turn directly to the reference rather than attempt first to classify it as Electrical Engineering, Civil Engineering, Mining Engineering, Mechanical Engineering, etc.

The work of regrouping the 12,000 items which form the 1919 Index has been done entirely by engineers, men familiar with the terminology of the profession and thus eminently qualified to compile a work of this character. No expense has been spared to make the 1919 Index an accurate and reliable compilation of intrinsic merit. It will be a book for the desk of the individual engineer as well as for the reference library—one which every practicing engineer should own.

## Conference on National Safety Codes

Within sixty days a definite start will be made in the development of uniform national safety standards, beginning with those subjects on which rules are now being formulated or revised by state or other authorities. This seems certain as a result of the Conference called by the Bureau of Standards and held at Washington, D. C., December 8 and 9.

This meeting was attended by about 100 representatives of the trade associations, engineering societies, state industrial commissions and labor departments, government officials, insurance companies and bureaus, and large employers of labor.

The program included an exposition of the large number and variety of conflicting safety codes in existence which have been formulated by various state, insurance, and other organizations, and an outline of the efforts which have been made to secure uniformity. It was evidently the unanimous feeling of those present that such uniformity had become not only extremely desirable but almost imperative, in view of the embarrassment and expense to which employers and others are subjected when different standards are enforced by different authorities, and when these standards are changed at, in some cases, frequent intervals. The Conference voted unanimously to approve the

plan of formulating safety standards under the general auspices of the American Engineering Standards Committee.

The vote of the Conference on December 8, already referred to, means that the formulation of uniform safety codes will be undertaken according to the regular procedure of the American Engineering Standards Committee as just described.

The Conference on December 8 further voted that to expedite early action, a general advisory committee should be formed to include representatives of all national associations, state commissions, and others legitimately interested, to survey the whole field of safety standards and recommend what standards should be undertaken first and what organizations should sponsor them. The conference recommended that such representative committee be organized by the National Safety Council, the Bureau of Standards, and the International Association of Industrial Accident Boards and Commissions, acting jointly. At an informal meeting of representatives of these three organizations, on December 9, plans were made for organizing the general advisory committee at once, and probably arranging for a meeting in January. Before this time, up-to-date information will be gathered as to what codes are now being written or revised in the various states and the general advisory committee will probably recommend that these subjects be given first attention. This committee will report to the American Engineering Standards Committee not later than February 1, and the definite assignment of sponsorships to the National Safety Council, the Bureau of Standards, and others will doubtless follow. The National Safety Council's participation in this work will be largely in the hands of the Engineering Section, in cooperation with the industrial sections especially interested.

## The Value of Sheet Asbestos on Hot Pipes

The following notes on recent research work carried on at the research laboratories of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., have been contributed by T. S. Taylor:

While conducting some simple tests on the relative thermal resistance of layers of asbestos paper when applied loosely and tightly, respectively, some rather interesting results were obtained. In the preliminary tests, it was observed that a bare tin vessel containing hot water would cool less rapidly than the same vessel when wrapped tightly with one layer of 0.013 in. sheet asbestos. This observation, which is just the opposite to the usual ideas held by most people, was carefully checked by fixing up identical tin vessels, one being left bare and the other covered tightly with sheet asbestos, and then obtaining the cooling curves for each when placed under similar conditions. The uncovered one cooled much more slowly than the one covered with asbestos. However, to obtain results from conditions more nearly like those met in practice, heaters were made so as to slip into vessels 4 in. in diameter and 20 in. long and the temperature excess of the air at the center of the vessel above room temperature measured, for various inputs and surface conditions.

From these tests, it has been found that an asbestos-covered hot-air pipe loses 33 per cent more heat from its surface than a bare one. To reduce the heat loss of the covered pipe so as to be equal to that of the bare pipe would require a coating of asbestos, as usually applied, at least  $\frac{1}{8}$  in. thick. To make the heat loss of the asbestos covered pipe  $\frac{3}{4}$  that of the bare one, would require a layer of asbestos about 1 1/8 in. to 1 1/4 in. thick. However, if the asbestos is put on loosely, three layers of 0.013 in. will reduce the heat losses to practically that of a bare pipe. Even with a dust-covered surface, such as usually exists on furnace pipes, the asbestos-covered pipe will lose at least 20 per cent more heat than the bare one.

The results show that it is not economical to cover hot-air pipes with the usual thin layer of asbestos, not only on account of the initial cost of labor and material but on account of heat losses later. Calculations based upon the data obtained indicate the possibility of reducing the heat losses so that there will be a saving of one ton of coal in sixteen. A more complete account of the experiments will appear shortly.

## Autogenous Welding of Boilers and Pressure Vessels

An important announcement has been received from the Steam Boiler and Fly-Wheel Service Bureau relative to the position it has taken in regard to autogenous welding in steam-boiler repair practice, at the suggestion of the Engineers' Committee of the Bureau. This Committee, which consists of representatives of all the insurance companies writing boiler insurance in the United States, has, in a report recently adopted unanimously, interpreted the application of Par. 186 of the A.S.M.E. Boiler Code on welding to boilers and other pressure vessels, for both new construction and repairs, in order to insure uniform practice in the acceptance of autogenous welding. Inasmuch as this report sets forth the position of the insurance companies with respect to the insurability of steam boilers repaired by autogenous welding, it is here reproduced with the permission of the Steam Boiler and Fly-Wheel Service Bureau.

By "autogenous welding" is meant any form of welding by fusion, that is, where the metal of the parts to be joined or added metal used for the purpose is melted and flowed together to form the weld. Such welding is accomplished by the oxy-acetylene, hydrogen or other flame processes, or by the electric arc; no distinction is made between any of these processes. The general rule to govern the acceptance of such welds in insured vessels is that prescribed by the Boiler Code of the American Society of Mechanical Engineers, Par. 186, as follows: "Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code, and where the safety of the structure is not dependent upon the strength of the welds."

The following illustrations will serve to point out where such work should be accepted or rejected.

1 Any autogenous weld of reasonable length will be permitted in a staybolted surface or one adequately stayed by other means so that, should the weld fail, the parts would be held together by the stays. It is necessary for the inspector to use judgment in interpreting the meaning of "reasonable length" as given above, since it may vary in different cases. In the average case it should be not more than 3 ft. Autogenous welding will not be accepted in unsupported surface.

2 The edges of the inner and outer sheets of vertical firebox boilers, or boilers of the locomotive type, may be joined by autogenous welding to form the door openings, if the surrounding surfaces are thoroughly stayed. This would also apply to other openings of a similar character in such surfaces.

3 For low-pressure plate-steel boilers operated at a pressure not exceeding 15 lb. to the sq. in., or for higher pressures in unfired vessels subjected to water pressure only, rectangular headers may be autogenously welded at the edges if the sheets are properly held together by stays. Autogenous welding of cracks and fractures in cast-iron boilers will not be permitted.

4 Fire cracks in girth seams extending from the edge of the plate to the rivet hole may be autogenously welded provided the cracks are properly prepared by cutting out the metal at the crack in the form of a letter "V" to permit fusion through the entire thickness of the plates. Similar cracks in girth seams located between the rivet holes may also be autogenously welded, provided the cracks do not extend beyond the edge of the lap of the inner plate. In the latter class of cracks it is advisable to drill a hole not exceeding  $\frac{3}{8}$  in. in diameter at the end of the crack before the weld is made. Cracks extending from rivet hole to rivet hole on girth seams cannot be welded. Calking edges of girth seams may be built up by autogenous welding between rivet holes and calking edge where the original section of the metal to be built up averages to be equivalent to one-fourth of the diameter of the rivet hole; and the portion of calking edge to be replaced does not exceed 30 in. in length in a girthwise direction. In all repairs to girth seams by autogenous welding the rivets must be removed over the portions to be welded and for a distance of at least 6 in. at each end beyond such portions. After repairs are made the rivet holes should be reamed before the rivets are redriven.

5 Stayed sheets which have corroded to a depth of not more than 40 per cent of their original thickness, may be reinforced or built up by autogenous welding. In such cases the stays shall come completely through the reinforcing metal so as to be plainly visible to the inspector.

6 Where tubes enter flat surfaces and the tube sheets have been corroded or where cracks exist between the tube ligaments, autogenous welding may be used to reinforce or repair such defects. The ends of such tubes may be autogenously welded to the tube sheets. The above-mentioned repairs for tube sheets and the welding in of the sheets, are not to be permitted where such sheets form the shell of a drum or boiler, as in the case of the Stirling type of boiler.

7 When external corrosion has reduced the thickness of plate around handholes to not more than 50 per cent of the original thick-

ness and for a distance not exceeding 2 in. from the edge of the hole, the plate may be built up by autogenous welding.

8 Pipe lines will be accepted where the flanges or other connections have been welded autogenously, provided the work has been performed by a reputable manufacturer and the parts properly annealed before being placed in position. Such welding when made with the part in place and unannealed will not be acceptable.

9 Autogenous welded-in patches in the shell of a boiler will not be acceptable regardless of the size of such patches. Autogenous welding of cracks in the shell of a boiler (except those specified in Par. 4) regardless of the direction in which they may lie will not be permitted, unless such welding is only for the purpose of securing tightness and the stresses on the parts are fully cared for by properly riveted-on patches or straps placed over the weld. The plates at the ends of joints may be welded together for tightness, provided the straps or other construction are ample to care for the stresses on the parts so welded.

10 Reinding or piecing of tubes for either fire-tube or water-tube boilers by the autogenous process will not be permitted.

## Electric Power for Holyoke, Mass.

Within recent months the Turners Falls, Mass., Company, which is the well-known hydroelectric development company on the Connecticut River and its tributaries, made a proposition to the city of Holyoke, Mass., for supplying the electrical energy to the present Holyoke municipal power-generating plant, the distribution of this power to be over the existing wires and equipment of the Holyoke plant and the latter to discontinue the generation of power. The consumption amounts to 60,000 kw. daily.

The limit of capacity of the Holyoke generating plant has nearly been reached, sufficient condensing water is not available and a very large new investment would be necessary in a few years if it should be decided to continue the manufacture of electrical energy. These considerations have aroused a great deal of interest among engineers in the Connecticut Valley. The newly formed Engineering Society of Western Massachusetts has taken an active part in the consideration of the matter and has participated in the public meetings which have been called by the city of Holyoke to discuss this subject. The result has been that S. M. Green, Mem. Am. Soc. M. E., consulting engineer of Springfield, Mass., was retained by the city of Holyoke to investigate the project and to render an impartial verdict.

John J. Kirkpatrick, manager of the Holyoke Gas & Electric Department and an active member of the Engineering Society of Western Massachusetts, has taken a leading part in the discussion of the problem and at the November meeting of the Engineering Society of Western Massachusetts in Holyoke, November 10, at the invitation of Charles L. Newcomb, the presiding officer, spoke upon the subject of municipal ownership, which had an interesting although not manifestly direct bearing upon this topic. Mr. Kirkpatrick said that while Holyoke was not imbued with socialistic tendencies, nevertheless it had been concerned in three very successful enterprises.

When but a town of 10,700 inhabitants, it spent \$375,000 in the construction of a railroad between Holyoke and Westfield to connect with the New Haven road and the Boston & Albany road.

Again, in 1872 the town voted to establish its own water-supply system and voted \$250,000 for this purpose.

In 1896 the Board of Aldermen passed the first vote favoring municipal ownership of the gas and electric plants. The law provides that a city shall not acquire a lighting plant until it has been so authorized by a two-thirds vote of its government passed in each of two consecutive years and thereafter ratified by a majority of the voters at an annual or special city election. In December, 1897, this ratification was secured. For the gas plant the city paid \$432,295 and for the electric stations \$377,252, both of which items included certain bonuses for mill powers. Subsequent enlargement of the plants brought their total value up to \$2,000,000.

Mr. Kirkpatrick said that the prices paid for street lights in Holyoke are the lowest in Massachusetts. If the city had paid for its lights during the past 16 years on the basis of the lowest price charged in any city or town in the state for metered electricity in buildings and for its street lights, it would have paid

\$453,745 more than they actually cost the city. The property of the Gas and Electric Department is not taxable, but if taxes had been paid during these 16 years they would have amounted to only \$358,134. While water power is used to a small extent, it is not an important element in the successful conduct of the plant. "The Gas and Electric Department, as it is known locally," he said, "is one of the most successful instances of municipal ownership in the country."

### Memorial to the Late Frederic R. Hutton

During the Annual Meeting of the A.S.M.E., as recorded in the account of the Business Session in this number, a tablet was unveiled of the late Frederic R. Hutton, for twenty-three years Secretary of the Society. This tablet, an engraving of which is reproduced herewith, was executed by Victor Brenner and now hangs in the reception hall of the Society headquarters. The tablet was presented with remarks by Major William H. Wiley, Treasurer of the Society, a close friend of Professor Hutton, and Acting Chairman of the Committee appointed for the preparation of this memorial. Major Wiley spoke as follows:

MEMORIAL PLAQUE TO THE LATE FREDERIC R. HUTTON

#### GENTLEMEN OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS:

In presenting this tablet, as Acting Chairman of the Memorial Committee appointed for that purpose, I was firmly of the belief that no words of mine would be fitting on such an occasion in speaking of a man so well known to the entire Society and whose work, as its Secretary and President, was a large part of the history of this organization, but the rest of the Committee unanimously differed from my judgment, hence I will yield to them and make a few brief remarks in rendering this memorial.

When Dr. Hutton became Secretary of the Society in 1883 the membership was 554. I was elected Treasurer in 1884 and the amount of money passing through my hands that year was, in round numbers, \$6,500. With his usual energy shown in every enterprise with which he was connected, Dr. Hutton labored in season and out of season to increase the membership of the Society by every means in his power, and used wonderful tact in all such action. Naturally a wonderful success resulted from his efforts.

The Society showed its appreciation of him and of his work by electing him to the presidency in 1908, at which time the membership was 2,929 and the amount of money passing through my hands, as Treasurer, was nearly \$54,000. I think I shall not say too much when I assert that a great part of the increase in membership was due to his untiring efforts. At the present time, the year ending September 30, 1919, the membership has increased to 11,082 and the

money passing through my hands, as Treasurer, \$375,430. I mention these figures to show that the growth fostered by Dr. Hutton was maintained by his successor.

My associations with Dr. Hutton, as Treasurer, were naturally intimate, and most pleasant. His energy is known to all of us, and as his neighbor in the Catskill Mountains for over twenty years, I can say that he threw his efforts in that section to building up and increasing the activities of the Union Chapel with which he was connected. He was busy at all times, and devoted a great deal of valuable time to this work, and, like his actions for the interests of the Society of Mechanical Engineers, his efforts in the Mountains were marked by signal success. I could dwell at great length on the work of Dr. Hutton, both professionally and socially. He has been sadly missed in this Society as well as in Twilight Park, his summer home. Notwithstanding he went to the Mountains for a well-deserved rest, yet when an appeal for any charitable object reached him, he did not hesitate to volunteer to aid as a reader or a speaker or a contributor. I am just glancing at these matters in passing to pay a deserved tribute to one who did so much for others, but the speakers who are to follow me will go more into the details of his work.

I cannot close more fittingly than to apply to our late Secretary and President, the words inscribed on the tomb of a celebrated architect who was buried near one of the finest structures he had ever erected—"If you wish to see his work, look around you."

### Engineers Honor Memory of John Ericsson

Tribute to the memory of John Ericsson, the inventor of the *Monitor*, and to Cornelius H. DeLamater, the founder of the DeLamater Iron Works, where much of Captain Ericsson's work was done, was paid by fourteen professional organizations at a meeting held on the evening of December 3. The exercises, which took place in the auditorium of the Engineering Societies Building, New York, were in commemoration of the eightieth anniversary of the meeting of Mr. DeLamater and Captain Ericsson and of the thirtieth anniversary of their death, for both men after thirty years of devoted patriotic service died within the same year.

Addresses were made by Mr. H. F. J. Porter, the Hon. Charles Vezin, Jr., a grandson of Cornelius DeLamater; the Hon. W. A. F. Ekengren, the Swedish Minister to the United States, and Rear-Admiral Bradley A. Fiske, U. S. N. (retired). A feature of the meeting was the singing of Mme. Marie Sundelius of the Metropolitan Opera and of Samuel Ljungqvist, formerly of the Royal Opera, Sweden. The Swedish Singing Society Lyran of New York also rendered several selections.

H. F. J. Porter, the first speaker of the evening, presented an illustrated lecture on The Phoenix Foundry and the DeLamater Iron Works. He outlined the careers of the two men who for over half a century were associated in work of lasting value to the engineering profession and to the country in which they lived. Under the direction of Captain Ericsson, the first river, lake, and ocean vessels driven by propellers were launched near the Phoenix Foundry, at that time located at 260 West Street, New York City. Captain Ericsson was also instrumental, during his years of association with Mr. DeLamater, in bringing about many important developments in naval architecture and marine and commercial engineering. At the DeLamater Iron Works there was also initiated under his direction such naval equipment as self-propelled torpedoes, torpedo boats, torpedo-boat destroyers and submarines. Here, too, the engines of the *Monitor* were constructed, as well as the first rock drills, the first air compressors and the first ice machines.

The Phoenix Foundry has long since disappeared; the DeLamater Iron Works has given place to a Cunard line pier, and Captain Ericsson's house was recently torn down to make room for a garage. But these historic sites will at least be marked for future generations, for the organizations under whose direction the memorial meeting was held will erect in the near future suitable tablets at all three places.

Following Mr. Porter, the Hon. Charles Vezin, Jr., spoke briefly of the life and work of his illustrious grandfather, Cornelius DeLamater. The Hon. W. A. F. Ekengren, Swedish minister to the United States, paid tribute to both men, and in reviewing the life and work of Captain Ericsson, said:

It is unnecessary for me to enter upon John Ericsson's career as

an inventor and upon the services he rendered the United States and humanity. They are too well known and too well appreciated to be forgotten. But there is one feature in his noble character which I should like to mention. While John Ericsson was always faithful to the country which he had chosen as his and did not hesitate to offer her his services and his life, he loved and honored his mother country, Sweden, and never failed to render it a service when he was able to do so. His *Monitor* which he invented long before it came to practical test, was intended for the coast defense of Sweden and when the first ship of this type was built for the Swedish Navy he presented the Swedish Government armament for it. John Ericsson has spread fame and glory over the Swedish name. In that respect as in so many others he ought to be an example worthy of aspiration for subsequent generations of Swedes in this country.

The last speaker of the evening was Rear-Admiral Bradley A. Fiske, U. S. N., retired, who characterized John Ericsson as a genius and declared that through his work the cause of civilization had been advanced. He said in part:

A more sudden and complete reversal of the conditions of a situation, cannot be found in history, or any one event more fraught with important consequences. The consequences that were to follow were perceived in their main features at the time, but their full value does not seem to have been realized. It was realized that the North could establish an effective blockade, but it does not seem to have been realized that this fact made it absolutely impossible for the South to win the war. Mahan was then an obscure young officer, and had not written his epoch-making book, *The Influence of Sea Power on History*; and the attention of the North was so wholly fixed on the movements of the armies, that no one seems to have apprehended the fact which is now so clear, that the weak point in the Confederate situation was their line of communication across the Atlantic Ocean, and that the victory of the *Monitor* made possible and even easy, the breaking of that line.

For this reason, sufficient advantage was not taken of the power the *Monitor* gave to the Union side, Ericsson's advice was largely disregarded, too few monitors were built, many faulty imitations were constructed that failed disgracefully; and almost the whole energy of the Northerners was devoted to widely scattered and relatively feeble military operations by soldiers whose only weapons were little muskets that they carried in their arms.

Even now, so imperfect a contrivance is the mind of man, the importance of the *Monitor's* victory is not realized, and it is deemed by many as of less importance than some of the land battles in which men were killed and wounded by the tens of thousands, with no special result beyond the killing and the wounding. Even great historians often fail to realize that the thing which makes a battle important is not the number of men engaged or killed or wounded, but the effect of the battle in winning or losing the war. Many of the most important battles have been comparatively bloodless, and many of the most bloody battles have been wholly decisive.

But while the most important result of the *Monitor's* victory was that it assured ultimate victory in the war to the Union side, it assured another important result, the increased power of navies and therefore the increased security of civilized and wealthy countries as against countries less civilized and wealthy. In other words, it assisted the cause of civilization, and the upward progress of the race.

It did this to a degree so great that it is hard to designate any other achievement that did more. As the *Monitor's* victory was due almost wholly to the genius and character of her designer, we can truly declare that no one man can be designated as having done more for the well-being of mankind than that brave and forceful and honorable and patriotic inventive engineer, John Ericsson.

### Lord Leverhulme's Six-Hour Day

Lord Leverhulme, the wealthy English manufacturer who has recently visited America, is best known in this country as an advocate of the six-hour day. What his viewpoint is, the extent to which he believes the six-hour day applicable and why he advocates the short day Lord Leverhulme explained in an address before the Boston Chamber of Commerce, reported in its journal *Current Affairs* for December 8, 1919.

His plan for the six-hour day contemplates operating in two shifts and in consequence a proportionate reduction in overhead. He says: "You will find that you can pay the same wages for six hours' work as for eight hours provided you work in two shifts of six hours each and that your result in product will not be increased in cost, merely through the increased output and the reduced fixed charges; and that to the extent that the fixed charges are greater than the weekly wage bill there will be an automatic decrease in cost."

Lord Leverhulme admitted that he did not believe the six-hour day was applicable to all industries,—at least at the present

time. He believes that it should be established in such industries as lend themselves for business reasons to its operations. If others follow it will be because the plan has succeeded by the sheer force of its own merit.

The strong appeal in the address was that portion devoted to a consideration of the place that domestic economy and home life should play in regulating the hours of labor in industry and it is probably this argument which would chiefly aid in selling the idea, at least in factory communities where parents and sons and daughters are all employed to a greater or less extent. He said one must remember that the housewife may have a husband and sons and daughters going to work and that their meals have to be provided for them when they return from their toil. They should go and come at times to fit in with the daily routine of the housewife, which answers the question so often asked, "Why not work two shifts of eight hours each instead of two of six hours each?" Starting early with the first six-hour shift, changing to the second at the middle of the day and completing the work early in the evening, enables a regular schedule of domestic economy to be maintained in the household, which cannot be done with the eight-hour shifts.

The guest of the Chamber of Commerce gave one warning. The plan must not be approached with the idea that it will make more money, although it may be based on the sound economic principles which make for success. The central idea of the scheme is the betterment of the conditions of industrial workmen, the making of better human beings and the realization that the road to success is along the line of our moral and spiritual resources.

## CAUSES OF INDUSTRIAL UNREST AND REMEDY

(Continued from page 23)

industrial establishments of the country, this situation would be intolerable. The employer would be bound by contracts he made, but the labor unions with whom he dealt would not be bound.

But in so far as the "open shop" is maintained, the employer, while he may suffer without redress from unlawful acts of the labor unions, is not called upon to make agreements with them at all and, therefore, insofar as contract relations are concerned, does not care whether or not they can be held responsible. It is his own men with whom he deals. While therefore it seems clear that from every point of view the law everywhere should be amended so that the labor unions should surely be responsible for their acts and for their contracts, the matter is of less importance if only the "open shop" can be maintained in full vigor.

The members of The American Society of Mechanical Engineers are a power in industry. Their influence pervades the industrial organizations throughout the land. Their interest in these great industrial questions is manifest. The membership of your Society in the National Industrial Conference Board is an evidence of this fact, for by becoming a member of that Conference Board your Society participates in a very definite, very honest and public-spirited effort to get at the real facts by investigation and research and to educate those engaged in industry as well as the public to a sound knowledge of the truth as to industrial questions, among the most important of which is that of the employment relation.

It is the duty of each member of this great body to study the question and to take a definite position as to what seems to be the single, important issue we are now facing. Shall our employment relations be developed on lines of trade-union domination, in which the employees are to be represented by the trade unions, working primarily for their own interests and the advancement of their own power on lines and by methods which to a large extent are economically, morally and legally unsound, or shall every effort be made to encourage the management of each industrial establishment to give itself wholeheartedly to the task of meeting its own employees in a friendly, sympathetic and conciliatory fashion, that by joint consideration of all questions of the employment relation, peace and contentment, coupled with the highest efficiency, may be attained?

## CHARLES DE FREMINVILLE ELECTED TO HONORARY MEMBERSHIP IN THE A. S. M. E.

TO the roster of illustrious men honored by The American Society of Mechanical Engineers is added the name of Charles de Freminville, engineer of the Schneider Works and member of the French Economic Mission.

Although so well known, the careers of famous men are always of interest and so a brief biographical sketch of this French engineer follows:

Charles de Freminville was born at Lorient, France, on August 18, 1856, from a family which has honored the engineering profession

CHARLES DE FREMINVILLE

for many generations. He obtained the degree of engineer at l'Ecole Centrale des Arts et Manufactures, an institution which all Americans who served in the artillery have learned to know and appreciate.

Soon afterwards he entered the service of the Paris-Orleans Railway, first as locomotive engineer and subsequently as designer and engineer. His knowledge of the English language determined his selection as the concern's representative at the Sharp Stewart Works of Manchester, England, in connection with an order placed at these works. This gave him occasion to study in all its details the practical operation of English railways.

Later on, by the request of the Orleans company, he visited America for the first time in 1885. He was accompanied by an intimate friend, Commandant Krebs, who together with Commandant Renard, played such a conspicuous part in the construction of the first dirigible *La France*, and who some years later also assisted in the construction of the first submarine *Le Gymnote*, under the direction of Gustave Zede. Mr. de Freminville was later to become the collaborator of Commandant Krebs during many years.

Having returned to France, the Orleans Railway Company commissioned Mr. de Freminville to design a new type of railway car following the lines of those used in the United States. He then designed an original type of car made almost entirely of steel, which was successfully adopted in Europe. American engineers noted this type of car with interest when they were compelled to renounce completely the utilization of wood in the construction of railway passenger cars.

In 1898 Mr. de Freminville again visited the United States with a view to studying the application of electric traction to the trains of the Orleans Railway Company.

Some time later he cooperated with his friend, Commandant Krebs,

who has assumed the direction of the Panhard and Levassor Works, with a view to manufacturing industrial types of automobiles, and particularly to organize production. His efforts were especially directed to the selection of metals for the construction of light machine parts which would nevertheless possess the required strength and rigidity. He had to make his selection among metals which were then new and the qualities and defects of which were little known and often misunderstood. The construction and operation of the automobile brought about a new conception of the resistance of materials.

In 1913, in response to an invitation of Dr. Frederick W. Taylor, Mr. de Freminville again visited the United States for the purpose of studying the scientific organization of workshops. This visit afforded him the opportunity of furthering his friendship with various engineers of the Pennsylvania Railroad and a number of automobile engineers of Detroit, and of visiting the laboratories at Harvard University where remarkable experiments on the action of high pressures on the resistance of materials had been performed by Professor Bridgman.

He returned to France and dedicated himself to the application and extension of the scientific principles of organization of workshops and, together with Prof. H. Le Chatelier, endeavored to attract the attention of French industrial manufacturers to the necessity of organizing their plants in order to obtain an intensive production. He emphasized always the great importance of the work done by Frederick W. Taylor, and undertook to show that it is necessary to take into account the human factor in the organization of the works.

When the war came he became engaged in the manufacture of projectiles. His attention was called to the solution of the many problems which arose from the fact that it was necessary to use steels coming from different sources; he also undertook to apply in the manufacturing operations the best methods of organization.

He was particularly successful in the reorganization of systems of work in the shipyards of Penhoet (St. Nazaire), which were converted into a school of application of scientific methods to the most varied kinds of work, such as the manufacture of machines and the construction of ships with all the specialties that such construction entails.

Mr. Eugene Schneider, desiring to make application of new methods in his establishments, which are by far the greatest industrial works in France, associated Mr. de Freminville permanently with the Schneider works after having made certain that under his influence the new ideas of organization were accepted by the personnel and effected important developments in production. Mr. de Freminville's task was singularly facilitated by the personal support of Mr. Schneider, who has known how to inspire his personnel with a faithfulness that is rarely found in industry.

Mr. de Freminville has been President of the Section of Transport of the Society of Civil Engineers of France. He is a member of the Council of the Society for the Encouragement of National Industry, of the International Association for the Standardization of Testing Methods, of the Taylor Society, etc.

### Resolution by Buffalo Section on Aims and Organization Report

At a meeting of the Local Section of the A. S. M. E. of Buffalo, November 18, 1919 the following resolution was presented and adopted:

Resolved, That the Buffalo Local Section of The American Society of Mechanical Engineers hereby approve the Report of the Committee on Aims and Organization as presented at the Spring Meeting; this Section considers that the work done by this Committee cannot but lead to broader opportunities and greater usefulness for our Society. This Section, however, cannot refrain from expressing its appreciation of the action taken in amending paragraph sixteen of the Report as presented at Detroit. We believe that The Journal can be made a means of far greater usefulness.

[The paragraph 16 referred to in the above resolution calls for the development and broadening of MECHANICAL ENGINEERING. The action at Detroit favored this, but advocated continuing the publication for the present as a monthly journal instead of publishing it weekly as recommended in the original draft of the report. The resolution above by the Buffalo Section, however, favors the full plan of development, which includes weekly publication.—EDITOR.]

# NEWS OF THE ENGINEERING SOCIETIES

Reports of Meetings of Electrical Engineers, Taylor Society, Engineering Society of Western Massachusetts, Railroad Fire Protection Association, National Founders' Association, etc.

## New York Section of the American Institute of Electrical Engineers

A meeting of the American Institute of Electrical Engineers was held at the Engineering Societies Building on the evening of December 10 for the purpose of organizing a New York Section of the Institute. The necessary formalities were carried out, by-laws were adopted, and the following officers were elected: Chairman, H. W. Buck; Secretary-Treasurer, H. A. Bratt; Executive Committee, the Chairman, the Secretary-Treasurer, E. B. Craft, W. S. Finlay and Farley Osgood.

There was no discussion regarding details of the work of the Section. The by-laws adopted provide that the Executive Committee of five should be the governing body and should manage the affairs of the Section. It is assumed that the scope of the Section will be identical with that of the other sections of the Institute throughout the country.

## Taylor Society

Endorsement of collective bargaining and of both trade unions and shop unions, the one to supplement the work of the other, was a prominent feature of the annual meeting of the Taylor Society, held at New York on December 5 and 6.

H. K. Hathaway, consulting engineer in management, Philadelphia, spoke on Standards: Their Nature, Purpose, Necessity. He observed that standards of accomplishment are dependent upon standards of equipment, materials, methods and product and that lower labor costs, which make higher wages possible, are brought about by such methods as continuous straight-line handling, elimination of waste motions, new machinery, keeping accurate records, reorganization of sales and improvement in stock-keeping. He gave concrete examples of ways of effecting economy by the installation of an automatic tool-grinding machine in a machine shop, by standardizing tools, by carefully regulating the tension of belts, etc.

Two committees were appointed, one to study "unemployment within employment" and reducing it to a minimum, and the other to provide for the introduction of courses in scientific management in university curricula.

## Naval Architects and Marine Engineers

The twenty-seventh general meeting of the Society of Naval Architects and Marine Engineers was held in New York, November 13 and 14.

The president of the Society called attention in his address to the recent surprising growth in American shipbuilding. He surveyed the situation in the industry from 1900 when 80 steel steam vessels of 168,000 tons were built as compared with Great Britain's figures of 567 vessels of 1,341,000 tons to the fiscal year of 1919 when the figures given, although they include only steel steamers of over 1000 tons, reached the total value of nearly 2,500,000 tons.

One of the professional papers described in detail the propelling machinery of the U. S. S. *Leviathan*, which is the largest vessel ever completed. The vessel is driven by the Parsons direct type of steam turbine arranged on four shafts and the turbine installation consists of eight separate turbines with their respective rotors. The go-ahead units, of which there are four, each driving a separate shaft, are arranged to operate in triple series; the go-astern units, of which there are also four, are arranged to operate in parallel and consist of two independent

sets for the two port and the two starboard shafts, each unit driving a separate shaft. The machinery installation is so designed that under any extraordinary conditions which may arise at sea it is possible to operate the two turbines of any one shaft entirely independent of the other units. Further, all interconnecting valves and piston are so designed as to permit carrying out any change at sea without having to shut down for any appreciable length of time.

Other technical papers were: Methods Employed in the Construction of Concrete Ships, by R. J. Wig; Submarines in General—German Submarines in Particular, by Commander E. S. Land; The Application of Standardization and Graphical Methods to the Design of Cylindrical Boilers, by H. C. E. Meyer; New Developments in High Vacuum Apparatus, by G. L. Kothny; and Standard Oiling System for Geared Turbines, by J. E. Schmeltzer and B. G. Fernald.

## Engineering Society of Western Massachusetts

Unusual interest both in the society itself and in the welfare of the community was displayed at the November 10 meeting of the Engineering Society of Western Massachusetts. This society was newly formed in the Spring of 1919 and an account of its organization meeting appeared in the July issue of MECHANICAL ENGINEERING, page 637. The officers of the Society are Charles L. Newcomb, Mem.Am.Soc.M.E., president; C. C. Chesney, vice-president; George E. Williamson, Mem.Am.Soc.M.E., vice-president; Winfield E. Holmes, Mem.Am.Soc.M.E., secretary and treasurer. The headquarters of the Society are in Springfield and its present membership, which includes engineers of all classes, closely approaches three hundred.

At the fall meeting were gathered engineers from all over Western Massachusetts. They spent the afternoon in visiting some of Holyoke's plants of engineering and industrial interest, where they were cordially received and shown all points of interest.

At the evening meeting, held at the Hotel Nonotuck, President Newcomb delivered an interesting opening address of welcome in which he touched briefly upon the engineering characteristics of Holyoke and its origin, founded upon its early and maintained water-power development and upon its dam, over a thousand feet in length, thirty feet high and with a potential horsepower of 45,000.

The principal speaker of the evening was H. W. Rogers of the Power and Mining Engineering Department, General Electric Co., Schenectady, N. Y., who delivered an illustrated address on Industrial Applications of Electric Power. Other speakers were John J. Kirkpatrick, manager of the City of Holyoke Gas and Electric Department, on Municipal Ownership of Public Utilities, and W. E. Holmes, upon the need of the active interest of members in the society.

A second meeting of the Engineering Society of Western Massachusetts was held on December 16 in Springfield, Mass., at which Charles Spofford, of Boston, Mass., spoke on Some Architectural Features of Boston Army Supply Base, and Fredric H. Fay, also of Boston, on The Proposed Springfield-West Springfield Bridge.

## Railroad Fire Protection Association

The best methods for handling and storing fuel oil and inflammable liquids were among the topics discussed at the annual meeting of the Railway Fire Protection Association held at Chicago

on November 18, 19 and 20. An extensive report specifying rules and regulations for the storage and use of fuel oil and for the construction and installation of oil-burning equipment was presented by the Committee on Oil-Burning Appliances.

A technical paper on Fuel Oil versus Coal for Locomotives, by A. M. Schoen, contained many recommendations concerning the various kinds of fuel oil, the methods of handling oil and the fire hazard involved. "The large tanks," according to Mr. Schoen, "should be at a distance of not less than 350 ft. from buildings or other combustible property, and this may well be made the minimum distance from the main line of the road as well, owing to the fact that should the tank be on fire and a strong wind blowing in the direction of the tracks, the burning gases and dense smoke could be driven a considerable distance, and if the tank is not sufficiently isolated the operation of the main-line trains might be affected for a considerable time. Also the tanks should be so located and protected that under no circumstances could the oil reach streams, either flowing or tidal, by means of which it might be carried into the proximity of destructible property. It is strongly recommended that the fueling of tenders by gravity pressure be avoided, in view of the danger of the entire contents of the tank escaping in event of accident. Most approved practices would require the oil to be pumped into the tender from reservoirs constructed below the grade level, which would permit of the flow being promptly shut off in event of accident to the piping or apparatus. These wells can be filled at regular intervals either by gravity feed from the large storage tanks or else direct from the tank cars. These underground reservoirs, if completely covered over, may be located at such points as may be most convenient for their intended purpose. Usually they should be constructed either of reinforced concrete or steel."

The report of the Committee on the Protection of Wooden Bridges and Trestles again recommended: That effective spark screens be provided in the front end of all locomotives; that ashpans and grates be made tight and kept in good working order; that special places be provided for the dumping of cinders and ashes, and that grates are not to be shaken down except at safe points; that all combustible refuse such as dry leaves, dead grass, weeds, brush and rubbish be cleared away from under and around all wooden bridges; that the decks of all wooden bridges, between the rails, be covered with No. 22 galvanized iron, this to prevent sparks from setting fire to the structure should they be dropped from the locomotive; and that all wooden bridges be coated with a fireproof or fire-retardant paint.

### National Founders' Association

The labor problems of the day were discussed at the annual meeting of the National Founders' Association, held in New York on November 19 and 20. President William H. Barr noted that 5800 strikes were called by the labor unions during the war, none of which occurred in non-union shops. He contended that more strikes are caused by the ill-advised conclusions or the hasty words of a foreman than through any other single cause, and advocated employee representation in order to reduce this possibility to a minimum by means of periodical meetings of foremen, discussion of policy, analysis of production plans and the emphasizing of the necessity of dealing justly with all employees.

Speaking on Industrial Unrest, George F. Monaghan, Detroit, counsel for the Association, suggested the employment of more efficient machinery and greater efficiency in management as remedies for the solution of present labor difficulties which he attributed to lack of production, the prevailing extravagance of all classes, socialistic agitation and profiteering on the part of both capital and labor. He also suggested that both employer and employee agree to adopt the present scale of wages and present profits until greater production can bring down the cost of living to the normal level.

The Industrial Association of Cleveland was described by H. P. Bope, vice-president of the Hydraulic Pressed Steel Co., Cleveland, as follows:

About five years ago ten of us got together to see how we could benefit our factory. First we realized the necessity to educate our foremen. Then we believed such a movement should not be confined to one factory, so we called together 50 leading business men of Cleveland and secured that number of members to form the association. There are 30,000 salaried employees in Cleveland and it was for their advancement as well as that of the employers that the movement was launched. A board of directors was formed, consisting of 25 employers and the same number of employees. We inaugurated monthly meetings with speakers and movies, a typical instance of the latter being a presentation of the manufacture of steel from the mining of the ore to the finishing of the steel product. Eight hundred men saw these pictures monthly. Last year in 20 meetings there was an average attendance of 1100 men—employers, superintendents and workmen. The object was to bring together the brains and the brawn and to distribute some of the brains into the brawn. The speeches were usually about 20 minutes long and were followed by an open forum. Cleveland is 500 per cent better off because of the industrial association. The foremen were broadened by mingling with the foremen of other shops and exchanging ideas and viewpoints. We have a magazine called *Coöperation*, which is very helpful in promoting friendly relations and affording education. We do not believe in unions—they are horizontal, whereas they should be vertical, or take it the executives and be local in their scope. We offset red propaganda by employing the vernacular of the laboring man in presenting economical truths.

Mr. Bope also referred to work being done to establish similar associations in Philadelphia, St. Louis and Detroit, and pointed out the advantages that could be derived by building a national association along the lines of the Cleveland Industrial Association.

Other papers were: Government Competition in Industry, by William H. Vandervoort; British and American Labor Problems, by Prof. J. Lawrence Laughlin; The Foreign Language Press, by Richard H. Waldo; and The Right of Individual Contract, by L. R. Clausen.

### National Advisory Committee for Aeronautics

At the annual meeting of the National Advisory Committee for Aeronautics, held in Washington on October 9, the general functions of the Committee were specified as follows:

- 1 Under the law the Committee holds itself at the service of any department or agency of the Government interested in aeronautics for the furnishing of information or assistance in regard to scientific or technical matters relating to aeronautics, and in particular for the investigation and study of problems in this field with a view to their practical solution.

- 2 The Committee may also exercise its functions for any individual, firm, association, or corporation within the United States, provided that such individual, firm, association, or corporation defray the actual cost involved.

- 3 The Committee institutes research, investigation, and study of problems which, in the judgment of its members or of the members of its various sub-committees, are needful and timely for the advance of the science and art of aeronautics in its various branches.

- 4 The Committee endeavors to keep itself advised of the progress made in research and experimental work in aeronautics in all parts of the world, particularly in England, France, and Italy, and will extend its efforts to the securing of information from Germany and Austria.

- 5 The information thus gathered is brought to the attention of the various subcommittees for consideration in connection with the preparation of programs for research and experimental work in this country. This information is also made available promptly to the military and naval air services and other branches of the Government, university laboratories, and aircraft manufacturers interested in the study of specific problems.

- 6 The Committee holds itself at the service of the President, the Congress, and the executive departments of the Government for the consideration of special problems which may be referred to it, such as rules for international air navigation, method of regulation and development of civil aerial transport, technical development policies of the military, naval, and postal air service, etc.

Dr. Charles D. Walcott was elected Chairman for the ensuing year, and Dr. S. W. Stratton, Secretary.

# GOVERNMENT ACTIVITIES IN ENGINEERING

*Notes Contributed by The National Service Committee of Engineering Council*

SEVERAL bills of interest to engineers have been passed by the House and will be taken up by the Senate during the next session. These bills deal with such matters as oil, gas and coal land leasing; water power; national budget; tariff on ores, glassware, instruments, etc.; railroads; minimum wages, and distribution of motor vehicles to State highway departments. The National Soldiers' Settlement Bill has been reported to the House but has not as yet been acted upon. The details of many of these bills were published in the November issue of *MECHANICAL ENGINEERING* and there follow some additional data and comments of more recent date.

## HIGHWAY LEGISLATION

The original bill proposing to create a national highway system controlled by a Federal Highway Commission, which was proposed by Senator Townsend, has been practically abandoned because of the opposition which has developed. It is now believed that any plan for National Highways constructed directly by the Federal Government will be unpopular with the states because only a limited portion of the state will be benefited directly by such highways. Further, the Government with its road building activities would be in competition with the states and the counties. It is believed that it will be easier for the Federal Government to hold the states up to a standard rather than to attempt to maintain the standard through its own work. No plans have been made to secure consideration of the Townsend bill at the present session of Congress.

Another highway bill which proposes a National Highway Department and Highway Commission has been introduced into the House, which aims to do away with the defects which have become apparent in the Townsend bill. It will bring the control of highway work more closely under the control of the states, at the same time giving enough Federal supervision to insure coordination and standardization in the work. The states are to be divided into ten regional areas with corresponding regional congresses having direct control of the work in their region but under the general direction of the National Highway Commission.

For the purpose of carrying out the provisions of this new act and as an initial appropriation for the creation of a National Department of Highways, the new bill proposes to appropriate \$10,000,000. The Secretary of Highways would receive \$12,000 per year and each National Highway Commissioner would receive \$6,000 per year.

## ESTIMATES FOR PUBLIC WORKS FOR 1921

The Secretary of the Treasury has approved and forwarded to Congress estimates for next year which total the unusually large sum of \$283,921,810. The appropriations for public works during the fiscal year 1920 total \$93,872,092. The estimates for work of particular interest to engineers and constructors are as follows:

Construction of Government buildings, including purchase of sites, \$1,332,775; marine hospitals and quarantine stations, \$5,204,621; fortifications, \$117,793,330; military posts, \$14,225,251; rivers and harbors, \$54,659,265; navy yards and stations \$20,600,000; Panama Canal construction and maintenance, \$18,245,791; depots for coal and other fuels, \$2,335,000; Reclamation Service, \$20,134,000; \$725,000 special appropriation for a fuel inspection system; \$1,865,886 for the Bureau of Mines; \$2,592,920, Geological Survey; \$3,000,000 (approximate), Bureau of Standards.

Engineering Council is an organization of national technical societies created to consider matters of common concern to engineers as well as those of public welfare in which the profession is interested. The headquarters of Engineering Council are located in the Engineering Societies Building, 29 West 39th Street, New York City. The Council also maintains a Washington office with M. O. Leighton, chairman of the National Service Committee in charge. This office is in the McLaughlin Building, 100 and G Streets, Washington, D. C. The officers of Engineering Council are: J. Park Channing, Chairman; Alfred D. Flinn, Secretary.

The Technical News Bulletin of the Bureau of Standards describes progress in the following work: Radio Fog Signalling Experiments; Standardization of Electron Tube Symbols; Scientific Research on Electron Tube Amplifiers; Magnetic Analysis; Industrial Safety Standards; Photoelectric Spectrophotometry; Reinforced Concrete Investigation; Concrete Tanks for Storage of Oil; Oxyacetylene Welding and Cutting Apparatus; Locomotive Packing Ring Investigation; Weights and Measures Publications; Testing of Hydrometers; Thermostatic Return Line Valves for Heating Systems.

## NOTES ON THE BUDGET, TARIFF, COMMERCE, ETC.

The Senate Budget Committee hearings, started Dec. 15, indicate a desire for the McCormick Bill. This bill provides a budget bureau in the Treasury which will cooperate with a budget officer in each department. The final budget shall be approved and sent to Congress by the President. The House Budget bill simply proposes to transfer the present work of the Treasury Department to the President, who will then prepare and submit an alternate budget with recommendations.

The office of the Adjutant General announces that its present policy governing the selection and appointment of members of the Officers' Reserve Corps contemplates the establishment of a competent Reserve Commissioned Personnel, individual members of which will be qualified to perform fully duties of their respective grades when ordered into active service in case of emergency. Officers commissioned in Officers' Reserve Corps to Oct. 31, 1919, numbered 52,839.

Contracts for electrical machinery for the propulsion of three new battleships have been awarded by the Navy Department. The price for the three sets is \$5,500,000. According to Navy officials, electrical propulsion has been successful. The *New Mexico*, which was the first electrically driven battleship, has given entire satisfaction, and the *Tennessee*, the second to be thus equipped, will shortly be put in commission.

The Bureau of Public Roads has announced that while expenditures during 1919 for hard-surface highways will set a new record with a total of \$138,000,000, this figure is small in comparison with the computed available total for 1920 of \$633,000,000, the spending of which promises to be dependent chiefly on the quantity of materials present limited railway facilities can transport.

The prohibition or control of importation of dyes and coal-tar products as provided in the trading with the enemy act are continued until Jan. 15, 1920, by the passage by the Senate of the House joint resolution. The question of tariff bills was discussed on the Senate floor, with the decision that they must go over until after other legislation is considered.

The Commerce Committee of the Senate has been urged by the Chief Signal Officer of the U. S. Army to extend American cables as an aid to the development of the nation's foreign commerce. This is in connection with the testimony providing new cable lines across the Pacific.

A Corps of Civilian Engineers in the U. S. Army is proposed in a bill which is aimed specially to care for the resident engineers throughout the country and the Washington force, who have been underpaid, although in charge of some of the most important river and harbor work.

Senator Thomas of Colorado, during the closing hours of the recent session of Congress, introduced a bill for the establishment of a trained body of 200,000 railroad workers, to constitute a railroad army reserve force subject to call by the Secretary of War in the event of nation-wide railroad strikes.

# LICENSING OF ENGINEERS

## Committee Appointed by Engineering Council Recommends Uniform Registration Law

**A**T a meeting held on October 25, 1918, Engineering Council authorized the creation of a committee to make a thorough study and submit a report on the subject of licensing or registering engineers. Fifteen engineers of long experience in the various branches of the profession of engineering were selected from 13 states representing practically all sections of the United States, as well as mechanical, electrical, mining, hydraulic, municipal, sanitary, railway and structural engineering and also colleges of engineering.

The personnel of the committee is as follows:

Theodore L. Condron, Chicago, Ill., *Chairman*

John W. Alvord, Chicago, Ill.	Caleb M. Saville, Hartford, Conn.
Bion J. Arnold, Chicago, Ill.	A. M. Schoen, Atlanta, Ga.
John H. Dunlap, Iowa City, Ia.	Francis C. Shenebrot, Minneapolis, Minn.
A. Lincoln Fellows, Denver, Colo.	Amos Slater, Seattle, Wash.
Farley Gannett, Harrisburg, Pa.	Christopher H. Snyder, San Francisco, Cal.
Arthur M. Greene, Jr., Troy, N. Y.	John W. Woermann, St. Louis, Mo.
James H. Herron, Cleveland, O.	
John Klorer, New Orleans, La.	

On December 18, 1919 this committee submitted its report to the Engineering Council, which included a "Recommended Uniform Registration Law," with the recommendation that the Council approve and endorse the bill for an act of legislation in each and every state for the regulation of the practice of engineering, architecture and land surveying. An abstract of the report is given below together with extracts from the recommended law, particularly those sections relating to the requirements for the registration of engineers.

On account of the overlapping of the work of engineers and architects in the design and erection of buildings and other structures and because of the close connection between this work and the surveying of the land and foundations upon which such structures are erected, it was deemed essential, as pointed out in the report of the committee, to provide in a single law for the registration of engineers, architects and land surveyors. By this means would not only life and health be protected but property rights as well, and to a fuller extent than if there were separate laws for each of these branches. The report was therefore carried through on this comprehensive scale, although the American Institute of Architects had previously prepared a "model law" to cover architecture and building.

### Abstract of Report on Licensing of Engineers

This preliminary investigation disclosed that very pronounced views were held by engineers throughout the country, both for and against state licensing or registration. The general sentiment one year ago was more opposed to such measures than it is today. The older members of the profession did not as a rule favor licensing nor did they feel there was need for state regulation of engineering practice, while among the younger men there was a feeling that licensing or registration by the states would add prestige to professional engineers and in many ways benefit the profession, as well as individual engineers.

The advantages claimed for state licensing or registration are the same as those presumably gained by the laws regulating the professions of law and medicine, namely, that those who are incompetent and unqualified professionally to practice are unable to obtain certificates or licenses and hence both the public and the profession are protected. On the other hand, those engineers who have already attained recognized professional standing feel they not only do not need the benefits claimed for such legislation, but they fear that state licenses or certificates of registration are apt to put the seal of state endorsement on men who do not deserve it and that the public would assume that a licensed or registered engineer was thereby certified by the state as fully quali-

fied, regardless of what might or might not be the requirements demanded before a license or certificate was granted.

However, the question has gone beyond the stage of debate, for already ten states<sup>1</sup> have enacted laws licensing or registering engineers, and other states are certain to enact similar laws during the present or coming sessions of their legislatures. In addition to these ten laws governing engineering practice, there are at least six states that require the licensing or registration of land surveyors, and in at least eighteen states<sup>2</sup> laws have been passed licensing or registering architects. Some of these ten laws are so drawn as to include both engineers and surveyors and some include engineers and architects and one or two include engineers, architects and surveyors. Moreover, these laws are not at all uniform and in several instances are likely to prove seriously embarrassing and annoying to engineers whose activities extend beyond the limits of a single state. Because of the nature of professional engineering work the practice of an engineer frequently extends over several states and therefore it is vitally important, if there are to be state regulations for engineering practice, that these regulations be made uniform so far as possible and that the engineering profession unite in wisely directing such legislation.

As stated, laws have been passed in at least 18 states for licensing or registering architects and the American Institute of Architects has endorsed and advocated such legislation, considering that both the architects and the general public are benefited thereby. Unfortunately some of the laws for licensing architects have been so drawn as seriously to interfere with legitimate engineering practice and the "model law" proposed and advocated by the American Institute of Architects contains definitions of "architecture" and "building" which, should such laws be passed and enforced, would prevent any one but a "registered architect" from planning or supervising the construction of any structure or any of the appurtenances thereto; consequently under this head would come a structure having simply foundations and girders, whether "with or without appurtenances." Under this model law proposed by the American Institute of Architects no one but a registered architect shall prepare plans for or supervise the construction of a building, and a "building" is thus defined in Section 19: "A building is any structure consisting of foundations, floors, walls, columns, girders, and roof, or a combination of any number of these parts, with or without other parts or appurtenances."

Since none but a registered architect shall have the right to design or supervise the construction of any structure or any appurtenance thereto, this matter becomes of vital importance to mechanical, electrical, sanitary and mining engineers, as well as to structural engineers.

In the State of Illinois a similar law for licensing architects was passed several years ago, the rigid enforcement of which made it necessary for engineers to unite in having a "structural engineers' license law" passed by the legislature, and now there are two laws in force in Illinois, one for architects, the other for structural engineers.

In some states the laws enacted and proposed are intended to regulate the practice of architecture, while in the other states laws have been enacted the purpose of which is simply to protect the term "architect," but not intended to regulate the practice of architecture. In Wisconsin and several other states no one may use the title "architect" without first obtaining from the state a certificate of registration as a "registered architect," but any one not an architect may prepare plans and supervise construction provided he does not style himself an "architect."

Therefore this committee at its meeting of October 13, 1919, adopted unanimously the following resolution:

<sup>1</sup>Colorado, Florida, Idaho, Illinois, Iowa, Louisiana, Michigan, Nevada, Oregon, Wyoming.

<sup>2</sup>California, Colorado, Florida, Idaho, Illinois, Louisiana, Michigan, Montana, New Jersey, New York, North Carolina, North Dakota, Oregon, Pennsylvania, South Carolina, Utah, Washington, Wisconsin.

The following is the sense of this committee relative to the desirability of a law licensing or registering engineers:

*Resolved:* That the enactment of legislation to provide for the registration of professional engineers is desirable and necessary. Ten states have already enacted such legislation. Laws licensing architects have been enacted in several states and similar laws endorsed by the American Institute of Architects, are pending in several other states, which, if enacted, would prohibit engineers from continuing their customary and recognized practice.

The only basis on which the practice of any profession may be subject legally to state regulation is "in order to safeguard life, health and property." Land surveying does not involve matters that would ordinarily jeopardize life and health, but property rights are vitally affected by land surveying, and many states have deemed it essential to place restrictions and safeguards about the practice of land surveying. Land surveying is associated with both engineering and architectural practice.

This committee has therefore deemed it advisable and to the best interests of all concerned to include in one law, provisions for the registration of engineers, architects and land surveyors. It has recognized that the practice of engineering and architecture overlap in many instances, especially in connection with the larger projects of modern structures, where many branches of the arts and sciences are combined, involving architecture, structural, mechanical, electrical, sanitary, and other lines of engineering.

There are ample reasons why architects alone should judge as to the qualifications of those desiring to practice architecture and why engineers alone should pass upon the qualifications of those desiring to practice engineering. Hence a bill for legislation has been drafted by the committee along these lines and it is confidently hoped that the objections expressed by the American Institute of Architects against laws which might provide jointly for the registration of engineers and architects will be overcome by the terms of the bill herewith submitted.

#### RECOMMENDED UNIFORM REGISTRATION LAW

This act is entitled "An act to regulate the practice of professional engineering, architecture and land surveying." Its sections deal with the enactment of the law, the appointment of a state board of registration for professional engineers, architects, and land surveyors, and the qualifications, expenses, certificates, powers, organization, meetings, receipts and disbursements, and records and reports of this board. Sections 9 and 13, extracts from which are here given, treat respectively of Application for and Issuance of Certificates, Exemptions, and Corporations or Partnerships, and the remaining sections take up questions of revocation and reissuance of certificates, the significance of the certificates, unlawful acts and penalties, public work, land surveying, and repeal of conflicting legislation.

#### APPLICATION FOR AND ISSUANCE OF CERTIFICATES

*Section 9:* The board shall, on application therefor, on prescribed form and the payment of a fee of \_\_\_\_\_ dollars (\$ \_\_\_\_\_), issue a certificate of registration:

*Note:* The application required should include a complete statement of an applicant's education and a detailed summary of his technical work. The statements made should be under oath, and should be supported by the recommendations of not less than two professional engineers, architects or land surveyors as vouches.

1. To any person who submits evidence satisfactory to the board that he or she is fully qualified to practice professional engineering, architecture or land surveying:

Provided, however, that no person shall be eligible for registration who is under twenty-five years of age, who is not a citizen of the United States or Canada, or who has not made declaration of his or her intention to become a citizen of the United States, who does not speak and write the English language, who is not of good character and repute, and who has not been actively engaged for six or more years in the practice of professional engineering, architecture or land surveying of character satisfactory to the board. However, each year of teaching, or of study satisfactorily completed, of engineering or architecture in a school of engineering or architecture of standing satisfactory to the board, shall be considered as equivalent to one year of such active practice.

Unless disqualifying evidence be before the board, the following "facts established in the application shall be regarded as prima facie evidence, satisfactory to the board," that the applicant is fully qualified to practice professional engineering, architecture or land surveying:

*Note:* When the law goes into effect a large percentage of practising engineers, architects and land surveyors will be registered to preserve the *status quo*. Long-continued practice, graduation from a technical school of approved standing with subsequent years of practice, or membership in high-grade technical societies, in the absence of disqualifying evidence, is accepted as *prima facie* evidence of qualification, as stated below.

a Ten or more years of active engagement in professional engineering, architectural or land surveying work:

b Graduation, after a course of not less than four years, in engineering or architecture, from a school or college approved by the board as of satisfactory standing, and an additional four years of active engagements in professional engineering, architecture or land surveying work:

c Full membership in American Institute of Architects, American Society of Civil Engineers, American Institute of Chemical Engineers, American Institute of Electrical Engineers, American Society of Mechanical Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Naval Architects and Marine Engineers, or such other national or state engineering or architectural societies as may be approved by the board, the requirements for full membership of which are not lower than the requirements for full membership in the professional societies or institutes named above.

Applicants for registration, in cases where the evidence originally presented in the application does not appear to the board conclusive or warranting the issuance of a certificate, may present further evidence which may include the results of a required examination.

*Note:* The standard of qualification is set high for two reasons: the public welfare will be better promoted by maturer competency; and the prestige attached to the term "Registered" will be more significant for the professional men themselves. In requiring the younger, less experienced men to serve somewhat longer as assistants or understudies to older men, no hardship is imposed which will not be compensated by the fuller return in recognition after registration.

In determining the qualifications of applicants for registration as architects, a majority vote of the architect members of the board only, shall be required; and in determining the qualifications of applicants for registration as professional engineers or land surveyors, a majority vote of the engineer members of the board only, shall be required.

#### EXEMPTIONS

*Section 13:* The following shall be exempted from the provisions of this Act:

Offering to practice in this state as a professional engineer, architect or land surveyor, by any person not a resident of and having no established place of business in this state.

*Note:* A professional card in a journal of national circulation is an "offer to practice" in any state in the Union. It would be considered an offer to conduct a professional man to registration in every state in which he may in this way, or by letter or otherwise, express his readiness to accept an engagement.

Practice as a professional engineer, architect or land surveyor in this state by any person not a resident in this state and having no established place of business in this state, when this practice does not aggregate more than fifteen days in any calendar year; provided, that said person is legally qualified for such professional service in his own state or country.

*Note:* It is a distinct advantage to the people of any state to be able to call in for consultation a specialist from any other state.

Such practice may be brief and often of an emergency nature.

Practice as a professional engineer, architect or land surveyor in this state by any person not a resident of and having no established place of business in this state, or any person resident in this state, but whose arrival in the state is recent; provided, however, such a person shall have filed an application for registration as a professional engineer, an architect or a land surveyor and shall have paid the fee provided for in Section 9 of this Act. Such exemption shall continue for only such reasonable time as the board requires in which to consider and decide upon the said application for registration.

Engaging in professional engineering, architecture or land surveying as an employee of a registered professional engineer, a registered architect or a registered land surveyor, or as an employee of a professional engineer, architect or land surveyor, authorized by paragraphs 2 and 3 of this section, provided that said practice may not include responsible charge of design or supervision.

Practice of professional engineering, architecture and land surveying solely as an officer or as an employee of the United States.

Practice of professional engineering, architecture or land surveying solely as an employee of this state or any political subdivision thereof, at the time this Act becomes effective and thereafter only until the expiration of the then existing term of office of such employee.

#### CORPORATIONS OR PARTNERSHIPS

A corporation or partnership may engage in the practice of professional engineering, architecture or land surveying in this state, provided the person or persons connected with such corporation or partnership in charge of the designing or supervision which constitutes such practice is or are registered as herein required of professional engineers, architects and land surveyors. The same exemptions shall apply to corporations and partnerships as to individuals.

## HENRY LAURENCE GANTT

ON November 23, 1919, H. L. Gantt died at his home in Montclair, N. J., after a brief illness. In his death the engineering profession has lost one of its foremost engineers, a pioneer in industrial management and a keen student of the human element in its relations to industry. He was associated with Frederick W. Taylor in his early work at the Midvale and Bethlehem Steel Companies and with this as a basis, and his personal ability as an organizer, he later established and successfully conducted his own consulting practice as an industrial engineer. His career was marked by original and thoughtful work, progressive in viewpoint, and effective in its accomplishment. In later years he developed a broad conception of industry as a national problem in which he regarded it essential that the man at the top should have the same close scrutiny and careful direction that has in the past been given his co-workers in the lower ranks. To these views he gave expression in a characteristically original manner in many addresses and written articles.

Henry Laurence Gantt was born May 20, 1861, in Calvert County,

HENRY LAURENCE GANTT

Maryland. He was graduated from Johns Hopkins as a Bachelor of Arts when only 19 years of age and taught for three years at the McDonough School in Baltimore County which he had attended as a boy. In 1884 he received the degree of Mechanical Engineer from Stevens Institute of Technology.

Following his connection with Frederick W. Taylor, he conducted his consulting practice until his death and had as clients more than a score of prominent manufacturing plants. Among these were the Westinghouse Electric and Manufacturing Co., American Locomotive Co., factories of Remington Typewriter Co., Bethlehem Foundry & Machine Co., Saco-Lowell Shops, Ingersoll-Rand Co., Amoskeag Mfg. Co., Cheney Brothers (silk manufacturers), Brighton Mills, Sayles Bleacheries and Corticelli Silk Mills.

Mr. Gantt was active in The American Society of Mechanical Engineers and served on the Council as Manager, 1908-11, and as Vice-President, 1913-15; on the Meetings Committee, 1912-17; and on the Executive Committee of this Council, 1913-14.

His papers contributed to the Society and which enrich its TRANSACTIONS comprise the following list, of which his early paper on the bonus system brought prominently to the front new features of management developed during his early work with Mr. Taylor: Steel Castings; Recent Progress in the Manufacture of Steel Castings; Bonus System of Rewarding Labor; Graphical Daily Balance in Manufacture; Training of Workmen in Habits of Industry and Cooperation; Mechanical Engineer and the Textile Industry; Modifying Systems of Management; Measuring Efficiency; The Relation Between Production and Costs; Productive Capacity a Measure of Value of an Industrial Property; Expenses and Costs; Efficiency and Democracy.

During the German trip of the Society in 1913 Mr. Gantt was a frequent speaker at the various functions and at the Leipzig meet-

ing of the Verein deutscher Ingenieure, held jointly with our Society, aroused much interest by his discussion of Scientific Management.

Mr. Gantt was also the author of three books: Work, Wages and Profits; Their Influence on Cost of Living; Industrial Leadership (Yale Lectures); and Organizing for Work. In addition, he contributed many articles to the technical and daily press.

There grew up around Mr. Gantt several groups having as their central thought the principles which he enunciated. Among these was a circle of friends who regarded service to the community as the essential element in industry, and which it was believed could be attained by concentrating on the production of goods rather than on the production of profits. It was considered that industry required a "new machine" rather than a disrupting social movement, and the movement was thus given this unique designation.

During the war Mr. Gantt acted in a consulting capacity, first for the Ordnance Department by invitation of General Crozier, who recommended for the entire War Department the use of Gantt's production charts, employed by Mr. Gantt in his work and which had been used in the Ordnance Department. These charts are well known among engineers and constitute an important development in recording the progress of work. When General Crozier was retired as Chief of Ordnance a change in plans was made, but the charts were later used by the U. S. Shipping Board and Emergency Fleet Corporation in routing ships and in following up constructive work.

Mr. Gantt's vision of a better spirit in industry is well expressed by the following quotations from his latest book, Organizing for Work: "The community needs service first, regardless of who gets the profits, because its life depends upon the service it gets. The business man says profits are more important to him than the service he renders; that the wheels of business shall not turn, whether the community gets the service or not, unless he can have his full measure of profit. He has forgotten that his business system had its foundation in service, and as far as the community is concerned has no reason for existence except the service it can render."

At the last Annual Meeting of The American Society of Mechanical Engineers Mr. Harrington Emerson presented a tribute to Mr. Gantt, extracts from which here follow:

## A TRIBUTE BY HARRINGTON EMERSON

Only a few weeks ago Mr. Gantt and I bent our heads over the same declaration of beliefs and principles, agreeing even as to words in the form it should take, a declaration of principles intended for the President, for Congress and for the people of the United States.

The old Hindu philosophy states that a man's full life is divided into four periods:

He is first a learner;

Next a doer;

He conquers the position of executive, of leader;

He becomes in the fullness of his experience a counselor.

When we were both still mainly in the doing stage, there was keen and friendly rivalry between us. It lasted into the executive stage, but as we slowly qualified to counsel, the agreement between us became close.

I regarded him as the nearest man to me, the man whose opinions I most valued, the man to whom I was most willing to turn for counsel. As we grow older many friends drop away. The more closely do old men cling to the few tried-out companions who remain.

It is my custom to place in my files a size-up, an appreciation of great men with whom I come in contact. This I find about Mr. Gantt:

An energetic, dominant nature;

Courageous and fearless, in expressing his opinions, which he never gave without careful consideration;

Very decided when once his mind was made up;

Industrious and energetic in working out a problem;

Independent in thought and action, ready in speech and quick and impulsive in manner, a clear thinker and a man of positive and decided character;

Precise and exact in his work and systematic in his activities, with a thoroughness in all his investigations, worthy of imitation and praise;

One of the great leaders in Efficiency.

At the extraordinarily early age of eighteen he had already received the degree of Bachelor of Arts from one of our youngest and greatest universities, he had already been in touch with the great living minds and through them, with the great minds of the past, and without this double opportunity any man, however naturally great, is burdened in the race. But he went on. He taught. He went to Stevens Institute; he was the student for even more than the first score of years. For the next twenty years he was a doer, little known to the wide world, but accumulating personal experience, trying himself out on new and difficult problems.

Leadership, authority, rests on the possession of four entirely distinct major qualities, and as to each I appraised Mr. Gantt. The first quality is that of goodness, of character, of good will towards his fellow man. It was this that attracted me to Mr. Gantt before I personally met him.

At the December meeting, 1901, of this Society, he presented a paper on A Bonus System of Rewarding Labor; with that clearness of thought which always characterized him, he stated in his second paragraph the aim of the system, which turned out to be the aim

of his own life. To harmonize the interests of the employer and of the employee; to give justice to the employee; to conform also to the best interests of the employer.

We have here Mr. Gantt's fundamental claim to leadership—*Harmony based on Justice*.

His last published utterance was in the *New York World*, Sunday, October 12, 1919. Speaking of industrial unrest, he said:

"No permanent peace is possible so long as one man is able to exploit the services of another for his own benefit."

In all his lectures and books in between these two dates he never deviated from the conviction of harmony based on justice. Therefore on this count of good will he was qualified as a leader.

The second qualification for authority, for leadership, is competence, is ability. The eminent position to which Mr. Gantt rose, his financial success, is the practical tribute paid to his competence and ability, but more than that his ability was recognized and deferred to by his own competitors in his younger days, his own friends in his last years.

The third quality essential to leadership is courage. Anybody who knew Mr. Gantt, who looked at his white head and heavy jaws and chin, knew that he was in the presence of a fighter.

He had physical courage;

He had mental courage;

He had spiritual courage.

There was never in anybody's mind any doubt as to where Mr. Gantt stood, whether he was leading you, at your side, or in behind you, you knew he was there and to be counted on.

The final quality essential to leadership, to authority, is personal charm.

We not only respected and depended on Mr. Gantt; we liked him. He could disagree without offending, and even in his wrath he was lovable. He furiously resented what he considered injustice, but he would come around into the wind as a full-sailed ship does turning a cape. Therefore we find in rugged form in Mr. Gantt that great quality of charm.

The noblest monument we can erect to him is to carry on his ideals. He had no faith in government machinery as government is at present organized.

His ideal held to and illustrated by his life should be ours: Harmony based on Justice.

## To Whom Credit Is Due

The social affairs of the Annual Meeting of the A.S.M.E., which were so great a success this year, as well as the professional features, were directly in charge of the Committee on Meetings and Program, the membership of which is Prof. Dexter S. Kimball, *Chairman*, Walter Rautenstrauch, A. L. DeLeuw, W. G. Starkweather, and R. V. Wright. As a result of experience in conducting previous conventions, an organization was perfected this year whereby a member of the Committee on Meetings and Program, Mr. R. V. Wright, was made general Chairman of a Sub-Committee for the Annual Meeting, with various sub-divisions devoted to the different activities.

Of these sub-divisions the general Social Functions were in charge of R. F. Jacobus, *Chairman*; President's Reception,

Frederick A. Scheffler, *Chairman*; Danee, E. Van Winkle, *Chairman*; Reunion, F. T. Chapman, *Chairman*; Acquaintanceship, Hazen G. Tyler, *Chairman*; Excursions, H. J. Marks, *Chairman*; Catering, Edric B. Smith, *Chairman*; Ladies, Mrs. H. C. Spaulding, *Chairman*. The President's Reception Committee was assisted by the Sections delegates who were present at the meeting, together with a number of the local members.

An effective department of headquarters was the Information Bureau to which Prof. Charles C. Spleff of Columbia University gave his personal attention, proving to be a second "Mr. Foster."

All of the events of the meeting were conducted with smoothness and in a way that created general satisfaction and gave the greatest possible pleasure to the guests in attendance. For this, credit should not only be given to the Committee on Meetings and Program, and the special committees mentioned, but to the personal efforts of Mr. S. N. Castle, of New York, who gave the results of his experience in his work in past years for the benefit of the committee members, and materially assisted in organizing and coordinating the work.

## Index to Volume 41 of Mechanical Engineering

An index to Volume 41 of MECHANICAL ENGINEERING is now in the course of preparation, which, it is expected, will be issued early in February. A copy of this index will be sent to each member of the Society or subscriber who sends in a written request therefor. In order that no more copies than are necessary to supply the demand may be printed, requests for copies should be received at headquarters not later than February 1.

## DREDGING PUMP OF NOVEL CONSTRUCTION

(Continued from page 7)

by Colonel F. B. Maltby and a careful study of the latter's paper in Vol. LIV, Trans.Am.Soc.C.E., has been of material assistance in the preparation of this paper. Colonel Maltby has also very kindly offered suggestions and criticisms during the preparation of this paper.

In a hydraulic pipe-line dredge of the cutter type it is believed that all passages through pipes and pump should be designed so that clogging at any point by more or less irregularly shaped solids will be reduced to a minimum. As a result of tests and also based on observation of the dredges in operation, it is the conclusion of the writer that the modifications described did not decrease the efficiency or capacity of the main engines and pumps, but did greatly increase the output of the dredges as excavating machines.

TABLE 3 DREDGING YARDAGES AND COSTS

Year 1918-1919	Yardage Excavated	COSTS							
		Arbitrary	Unit Cost	Charter	Unit Cost	All Other Charges	Unit Cost	Total	Unit Cost
May, June and July	333,643			74,887.19	.196	12,143.72	.031	87,030.89	.227

# LIBRARY NOTES AND BOOK REVIEWS

**THE ANALYSIS OF MINERALS AND ORES OF THE RARER ELEMENTS.** For Analytical Chemists, Metallurgists, and Advanced Students. By W. R. Schoeller and A. R. Powell. J. B. Lippincott Co., Philadelphia, 1919. Cloth, 6 x 9 in., 239 pp., tables.

This is a practical laboratory guide for those interested in the determination of the so-called rare elements, and is the first work, the authors state, in which the complete analysis of the minerals of these elements has received systematic treatment. The methods have been selected from various authorities, supplemented when necessary by methods devised by the authors. Full details are given in each case.

**ASBESTOS—FROM MINE TO FINISHED PRODUCT.** Asbestos and Mineral Corporation, New York, 1919. Cloth, 10 x 11 in., 194 pp., 60 pl.

A collection of sixty photographs of asbestos minerals, mines and manufacturing plants, forming a pictorial presentation of the mining of raw asbestos and its manufacture into finished goods. Brief explanatory notes accompany the illustrations.

**CATALYSIS IN INDUSTRIAL CHEMISTRY.** By G. G. Henderson. Longmans, Green & Co., New York. Cloth, 6 x 9 in., 202 pp.

This, the latest volume of the series of Monographs on Industrial Chemistry which is being published under the editorship of Sir Edward Thorpe, is intended to present broadly our present knowledge of the phenomenon of which it treats. The book reviews the existing literature on catalysis, paying particular attention to the many and varied applications now used in industry. The author hopes that it will also suggest the desirability of further investigations.

**COMMERCIAL OILS—VEGETABLE AND ANIMAL.** With special reference to Oriental Oils. By I. P. Lavick. First edition. John Wiley and Sons, Inc., New York, 1919. Cloth, 5 x 8 in., 138 pp.

This book is intended to give men without technical training, who are in the oil trade, the technical data and information required in everyday dealings, in concise form. The various commercial oils are listed. For each are given the sources, uses, and the physical and chemical characteristics. The values have been collected from the standard texts, supplemented, particularly in regard to oriental oils, by the results obtained in the author's laboratory.

**THE CONDENSED CHEMICAL DICTIONARY.** A reference volume for all requiring quick access to a large amount of essential data regarding chemicals, and other substances used in manufacturing and laboratory work. Compiled and edited by The Editorial Staff of the Chemical Engineering Catalog. The Chemical Catalog Company, Inc., New York, 1919. First edition. Cloth, 6 x 9 in., 325 pp.

This volume has been prepared to meet the need for a concise summary of the properties of chemicals. The arrangement of the book is alphabetical. The information given includes variant names, formulas, color and properties, constants (boiling and melting points, specific gravity, etc.), derivation, method of purification, grades obtainable, containers, uses, fire hazard and shipping regulations. Substances made in America are indicated. The volume is fully cross-indexed, and includes a number of useful tables of weights and measures, thermometer scales, etc. Synthetic dyes are omitted. While the compilers state that no attempt has been made to be exhaustive, but merely to give the outstanding facts concerning the chemicals ordinarily met in commerce, approximately six thousand substances are included.

**ELEMENTS OF RADIOTELEGRAPHY.** By Ellery W. Stone. D. Van Nostrand Co., New York, 1919. Flexible cloth, 5 x 8 in., 267 pp., 125 illus., 33 pl.

This book, by the instructor at the U. S. Naval Radio Station, San Diego, was written primarily for use in instruction at that school; it is believed, however, that it will be helpful in other schools and for self-instruction. The physical rather than the mathematical presentation of the subject is used. A knowledge

of physics and mathematics is not necessary. Prominence is given to the development of the subject as illustrated by patents.

**FIFTY YEARS OF IRON AND STEEL.** By Joseph G. Butler, Jr. The Penton Press, Cleveland, 1919. Leather, 6 x 10 in., 145 pp., portraits.

This volume is one of a special edition, limited to one hundred copies, of an address delivered before the American Iron and Steel Institute in 1917, in which the author gives his personal reminiscences of the development in iron and steel making as observed during an active participation in the industry in eastern Ohio, which began in 1857. To this are added some brief data on the early history of iron and steel, and a chapter on the activities of the American iron manufacturers during the great war. The volume is profusely illustrated with portraits of men of note in the industry.

**FOREST PRODUCTS. Their Manufacture and Use.** Embracing the Principal Commercial Features in the Production, Manufacture, and Utilization of the Most Important Forest Products (Other than Lumber, in the United States. By Nelson Courtlandt Brown. First edition. John Wiley and Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 471 pp., 120 illus., 1 pl., tables.

The object of this book is to provide a brief account of the chief commercial features involved in the manufacture and use of such products as wood pulp and paper, tanning materials, veneers, cooperage, naval stores, distilled products, charcoal, maple sugar and syrup, dye woods, rubber, cork, excelsior, shingles, nine timbers, etc., which will serve as a text for students and as a book of reference. The volume reviews a field in which, the author states, but little has been written on American practice. Brief bibliographies are appended to the chapters.

**GEODESY.** Including Astronomical Observations, Gravity Measurements, and Method of Least Squares. By George L. Hosmer. First edition. John Wiley & Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 368 pp., illus., tables.

The author has endeavored to produce a textbook adapted to a course of moderate length which would make clear the underlying principles and emphasize the theory as well as the details of field work. The methods of observing and computing given are consistent with the practice of the Coast and Geodetic Survey.

**HAND-BOOK OF FIRE PROTECTION.** By Everett U. Crosby, Henry A. Fiske and H. Walter Forster. Sixth edition. D. Van Nostrand Company, New York, 1919. Flexible cloth, 5 x 7 in., 737 pp., illus., tables.

This work has long been a standard reference book for insurance engineers and inspectors, in which those methods of fire protection which have crystallized into good practice are collected and presented concisely. The present edition has been enlarged by new chapters and illustrations, and has been carefully revised.

**HYDROLOGY.** The Fundamental Basis of Hydraulic Engineering. By Daniel W. Mead. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 647 pp., illus., maps, tables.

Lack of knowledge of the fundamentals of hydrology and of the importance of hydrological factors has been responsible, the author believes, for more failures in hydraulic-engineering projects than defects in structural design. To assist in removing this ignorance he has here set down some of the more important facts and principles, omitting everything that his long experience has not shown to be of practical importance. Carefully selected lists of references are appended to each chapter, to enable readers to complete their study of any phase of the subject which has not been sufficiently treated within the limits of the book itself.

**A MANUAL OF PHYSICAL MEASUREMENTS.** By Anthony Zeleny and Henry A. Erikson. Fourth edition. Cloth, 5 x 8 in., 261 pp., 129 illus., tables.

This manual is an outline of the laboratory course given to students of general physics at the University of Minnesota. One hundred and thirty-three experiments are included. Directions

for assembling the apparatus and performing the experiments are given. Appendices give the mathematical tables needed by users of the book.

**THE METALS OF THE RARE EARTHS.** By J. F. Spencer. Longmans, Green & Co., New York, 1919. Cloth, 6 x 9 in., 279 pp., diagrams, tables.

This volume supplies a review of our knowledge of these metals, in which their occurrence, separation, compounds and uses are described. An extensive list of references is included, which contains, the author believes, all the important papers published on the subject, as well as most of those of lesser importance.

**OPPORTUNITIES IN CHEMISTRY.** By Ellwood Hendrick. Harper and Brothers, New York, 1919. Boards, 5 x 8 in., 102 pp.

This little volume attempts to explain the relation of chemistry to our activities in general and the usefulness of chemical knowledge in various walks of life. It will serve to introduce the subject to those considering its possibilities as a profession.

**OSMOTIC PRESSURE.** By Alexander Findlay. Second edition. Longmans, Green & Co., New York, 1919. Cloth, 6 x 9 in., 116 pp., illus., tables.

The author of this monograph gives an account of the theories of osmotic pressure, the methods of determining it, and the general theory of solutions. An extensive bibliography is included. In preparing this new edition account has been taken of the results obtained by investigators during the past six years.

**THE OUTLOOK FOR RESEARCH AND INVESTIGATION.** With an Appendix of Problems Awaiting Solution. By Nevil Monroe Hopkins. D. Van Nostrand Company, New York, 1919. Cloth, 5 x 8 in., 241 pp., 1 pl., 6 portraits.

The object of this book is to stimulate a more general interest in American research, to indicate its necessity at this time, to explain the educational requirements for research workers and to point out the ways in which such work is done inefficiently at present. Appended to the volume is a list of suggested lines of research.

**THE PHYSICAL CHEMISTRY OF THE METALS.** By Rudolph Schenck. Translated and annotated by Reginald Scott Dean. First edition. John Wiley and Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 239 pp., illus., tables.

This volume is the outcome of a course of lectures delivered in the Technischen Hochschule at Aachen before the engineers of the district. The purpose of the lectures was to show the use of chemical statistics and to explain the applications of physical chemistry in the study of smelting operations and metallurgical processes. The translator has made additions to the original text when necessary and has revised the numerical data to agree with the accepted values.

**PRACTICAL MATHEMATICS FOR HOME STUDY.** Being the essentials of Arithmetic, Geometry, Algebra and Trigonometry. By Claude Irwin Palmer. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 5 x 8 in., 493 pp., illus., tables.

During the past fifteen years the author has taught mathematics in the evening school at the Armour Institute of Technology to classes of men engaged in practical pursuits of various kinds. For this purpose a course of instruction was published in four volumes, which has now been arranged in one volume, with particular reference to the needs of home students. In the present edition, a few new topics have been added, together with many solutions of problems. The book includes arithmetic, geometry, algebra, logarithms and trigonometry. It is intended for adult students and the three thousand exercises and problems are selected to illustrate actual practical problems.

**PRACTICAL WINDINGS OF ALTERNATING CURRENT MACHINERY.** By J. Herbert Wickham. J. H. Wickman, Milwaukee. Paper, 6 x 9 in., 36 pp.

This pamphlet is intended to give the necessary information to armature winders, without mathematical calculations or theoretical discussions. Directions for winding, reconnecting for other voltages or changing the windings from one phase to another are given.

**PRINCIPLES OF DIRECT-CURRENT MACHINES.** By Alexander S. Langsdorf. Second edition. McGraw-Hill Book Company, Inc., New York, 1919. Cloth, 6 x 8 in., 400 pp., 314 illus.

This book has been prepared to place before students of electrical engineering a reasonably complete treatment of the

fundamental principles underlying the design and operation of all types of direct-current machinery. Instead of attempting to touch the "high spots" in the whole field of direct-current engineering, attention has been concentrated upon certain important features which are ordinarily dismissed with brief mention, but which, the author believes, are vital to a thorough grasp of the subject. The present edition has been thoroughly revised and enlarged in accordance with the results of experience in the use of the book.

## SYSTEMS FOR MUTUAL CONTROL OF INDUSTRY

(Continued from page 25)

labor managers together have what they call a Board of Labor Managers.

"When there is to be a general revision of wages or hours, or a new agreement is to be made, the Board of Labor Managers and the representatives of the Union Joint Board meet and work it out. When there are adjustments to be made, that apply to only one shop, the individual or group of employees affected takes it up with the labor manager of the plant and assistance may be given by the Section or shop chairman. If a satisfactory adjustment cannot be made, one of the managers or deputies of the Joint Board is called in. In the vast majority of cases, amicable adjustments are arrived at. Where such an agreement cannot be reached, the matter is left to impartial arbitration, for which permanent machinery is created by the industry itself—in effect an industrial court.

"The employers' association of each city, together with the joint board of the Union, select an impartial person to act as judge of all disputes. Technically he is the Chairman of a labor adjustment board, consisting of the labor managers and the union representatives who argue cases before him. His salary and the expenses of his office are paid half by the employers and half by the unions. He hears no cases of men who have stopped work. Strikes are illegal. The employer may suspend a worker, but if on appeal to the Chairman, this dismissal is found unjustified, the employee is reinstated and must be paid by the employer for the time he lost. This is the machinery of democracy. The institution of the impartial chairman or judge, is a recognition that law, order and government must prevail in industry, that peace must be maintained and the interests of the public conserved. But all this is not enough. With each market organized separately, employees complained that the same work was paying more in one place than in another, and there was a constant tendency to upset the wage agreements. The union, therefore, agreed with the employers, that a national plan of collective bargaining must be devised in order to stabilize labor conditions. A few weeks ago representatives were elected by the National Association of Clothing Manufacturers and the National Union, to form a joint industrial council for the entire industry, and they are now working on a national agreement to apply to all markets."

Dr. Leiserson stated that although this plan has not solved the whole labor problem, or eliminated all labor troubles, it has shown that war is not necessary to settle labor disputes. "The plan is beyond the experimental stage," said Dr. Leiserson, in conclusion, "It began five or six years ago in the Ha't, Schaffner & Marx factories of Chicago, and the success of it in these factories, has spread it through the entire industry. It has taught the employers to respect union leaders whom they once thought were crooked advocates and it has made unions and their leaders have confidence in their employers and cooperate with them. It has enabled unions and employers to work together on such problems as the elimination of strikes, the introduction of machinery, time studies and standardization of occupations, increasing production and maintaining shop discipline. Disputes on all these questions have not been eliminated. They never will be; but they have been settled, in a peaceful, orderly manner according to laws of the industry, which labor and capital alike have had a share in framing. More than all this, however, the plan has enabled the unions to take on a peaceful character and to concern itself with the real problems of collective bargaining instead of emphasizing war policies as they have to do as long as employers fight them."

# MECHANICAL ENGINEERING

THE JOURNAL OF THE AMERICAN SOCIETY OF  
MECHANICAL ENGINEERS

Volume 42

February, 1920

Number 2

## An Improved Weir for Gaging in Open Channels

By CLEMENS HERSCHEL, NEW YORK, N. Y.

*In the following paper are presented the results of a series of investigations on weirs which should mark an epoch in the measurement of water by that means. Asked by the Power Test Code Committee of The American Society of Mechanical Engineers to advise it with regard to weir measurements, and supplied by Engineering Foundation with the necessary funds to conduct the experiments, the author devised an entirely new weir which was tested in the Hydraulic Laboratory of the Massachusetts Institute of Technology. The tests revealed that for discharges of from 0 to 9.55 cu. ft. per sec. per ft. of weir length, the limits covered by the experiments, the quantity of water flowing,  $Q$ , was directly proportional to the difference,  $d$ , in two pressures, one measured just upstream of the weir—corrected automatically for the velocity of approach, and the other measured at the crest, the formula being:  $Q=5.50 d$ . The weir, which bears no resemblance to the sharp-edged weir now in use, has a 2:1 slope of approach to the crest. The crest is made in the form of an arc of a circle and is hollow for observing the pressure at that point. The nappe of the stream is supported for a short distance beyond the crest by another 2:1 slope. The paper opens with a résumé of the history of weir measurements and contains descriptions and diagrams of the apparatus and tests of the new weir, with tabular and graphic reports of the results obtained.*

"Daniel Bernoulli often said to me to eschew all those complicated formulae; he believing that nature works according to laws that are too simple to lead to them; and if one finds such, that it is because one's computations have been based on false preliminary assumptions."—R. Wolf. *Biographies Relating to the History of Civilization in Switzerland*, Vol. 3, (1860), p. 176.

TO ANY ONE whose memory of hydraulic engineering in the United States, more especially in New England, runs back 60, or only 50, years, the standing at that time of the "Francis formula" for weir discharge will appear as little short of infallibility, or of perfection. Courts of justice recognized it as decisive; lawyers of eminence played with it as though it were one of the choicest morsels from the tree of knowledge; it was the last word in gaging the flow of water. And there was reason for such an estimate of its value at the time.

James Bicheno Francis was then easily the leading hydraulic engineer in the United States, with perhaps not over half a dozen of the species in the whole country. Grappling as a young man with the problem of insuring their lawful quantities, day by day, to each of the seven "Proprietors of the Locks and Canals on Merrimack River," at Lowell, Massachusetts, out of the common trough or canals which fed them collectively, he may be said to

have been the first one who thus brought order out of the disorder which that communistic distribution of water—naturally accompanying the American system of power distribution canals for manufacturing purposes, and now passing away in favor of the electrical distribution of power—always brings with it. For the purpose named he instituted, about 1850, the series of hydraulic experiments described in his book entitled *Lowell Hydraulic Experiments*; and he did this with all the accuracy obtainable at the time and place that has been named.

From another point of view than just described were his experiments of a new order of importance. If any one will consult Weisbach's *Experimental Hydraulik*, or the later editions (1855-60) of Weisbach's *Mechanics*, he will be surprised at the Lilliputian dimensions of the apparatus then in vogue as the basis of engineering knowledge for use in the practice of hydraulics. Thus Weisbach's experimental reservoir had an area of 1.35 sq. ft.; and his ajutages were ordinarily about three hundredths of a foot in width, or diameter. Of course, we know that Atwood's machine, of extremely moderate dimensions, will measure the force of gravity exercised by the globe which we inhabit; but it requires more confidence in the "horse sense," no less than the technical ability of hydraulic engineers, than is possessed by the average mill owner or his agent to give him confidence in the work of the engineer he employs, should that engineer base it on experiments such as inspired Julius Weisbach or his immediate disciples. So that the experiments of Francis, conducted out of doors on a scale commensurate with their importance, at the lower locks of the Concord River, came to the interested "Proprietors" and others as a refreshing and new conquest of mind over matter. They were much more reliable because made on a natural scale; exact, as every one could appreciate, from the care taken in making the experiments and the computations following the experiments, and thoroughly reliable.

At that time arose the expression, "made with a standard weir," which has remained alive to the present day, although, as will presently be seen, there was no propriety whatever for calling any weir a "standard." The only standard water-gaging apparatus is a tank or reservoir. Weirs, orifices, venturi tubes and meters, and other water-gaging apparatus and methods, can only become truly rated by comparison with tank measurements, and thus thereafter competent to give reliable service. Such comparisons, moreover, establish the degree of reliability of the several methods that have been subjected to comparison, and from this point of view the weir has for many years been falling into deserved disrepute.

To treat the matter somewhat chronologically, there is the article in *Engineering News* for November 10, 1898, by the present writer, protesting against the multiplicity of formulae that sharp-edged weirs and orifices, and present methods of observing heads upon them, bring in their train; and suggesting that observations be taken at the weir or orifice, and that weirs and orifices cut "in a thin plate" be abandoned.

In the Transactions of the American Society of Civil Engineers for 1914, the discussion on the paper of R. R. Lyman, Mem. Am. Soc. C.E., brought out clearly the number of methods there were in use to measure "head upon the weir," and their idiosyncrasies.

<sup>1</sup> Hydraulic Engineer, 2 Wall Street. Past-President, Am. Soc. C.E.

<sup>2</sup> "M. D. Bernoulli mal souvent dit de me défer de toutes ces formules compliquées; il croit que la nature est trop simple pour y mener; et que si on en trouve, c'est qu'on a fondé ses calculs sur des fausses hypothèses."—R. Wolf, *Biographien zur Kulturgeschichte der Schweiz*, Band 3 (1860), p. 176.

Abstract of a paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

These several methods go far beyond any forethought of the pioneer experimenters in that sort of work, and definitely confirm the rule that when any one formula is to be used to compute weir discharge, the weir and methods of taking observations of flow over it must imitate with slavish exactness the construction of the weir and methods of taking observations that were followed in constructing the selected weir formula, a matter of annoyance or difficulty as a rule.

Fteley and Stearns, for example, *Trans.Am.Soc.C.E.* for 1883, p. 5, say: "It is, however, almost impossible to cover all cases that may occur in practice."

Bazin, in his 1890 article, Part I, for that year, of *Annales des Ponts et Chaussées*, p. 4, and elsewhere, says that to attempt to experiment on all cases possibly to be met with in practice (instead of setting up a standard form to be used in such work) must be pronounced impracticable. And in his 1898 article, Part II for that year, p. 161, he says: "Each type of weir would therefore require a special study; and face to face with a complexity like this, one must abandon the idea of establishing formulæ for general application."

R. E. Horton, *Trans.Am.Soc.(C.E., 1914, p. 1300*, tells us that "of the making of many formulæ there is no end." Also, p. 1326,

be automatically corrected for "velocity of approach," if one pleases, or corrected by computation before being used in the above formula, if preferred), and the other taken at the crest. In both cases  $d$  is obtained by measuring the elevation of a water surface in a pail by means of a hook gage, or otherwise as desired. This difference of pressures may also be obtained by means of one of the many devices already invented and on the market for measuring differences of pressure, in which case the register may indicate mechanically the quantity passing at any moment, sum it up for any given period of time, portray it graphically on a chart, or simultaneously do all three of these recording operations.

It will be observed that the process just described is not open to the criticism of R. E. Horton, mentioned above, who said: "No one equation, of the form he (Francis) uses,  $Q = mh^N$ , can fit accurately a series of experiments on weirs of the type (sharp-edged weirs) herein considered." It does this, moreover, with the added simplicity of making the exponent  $N$  equal to 1.

And the reason it does all this is because it is carried out with a weir that is not a "sharp-edged weir," the type that has rested like the incubus of an evil spirit upon the minds of all hydraulicians for full 200 years, ever since the Marchese G. Poleni first wrote about weirs in *De Motu Aquæ Mixto*, Patavii, 1717. Bazin

FIG. 1 DIAGRAMMATIC REPRESENTATION OF THE EXPERIMENTAL APPARATUS

"If Francis had used higher and lower heads, he would have discovered that no one equation of the form he uses,  $Q = mh^N$ , can fit accurately a series of experiments on weirs of the type herein considered."

Hamilton Smith<sup>1</sup> saw this, and very likely Francis did, for Francis was very particular to state that the formulæ he gives must only be used between stated limits of head, and only upon fulfillment of other stated conditions of weir construction and operation.

Finally, in the discussion on the Paper by Floyd A. Nagler, *Trans.Am.Soc.C.E.* for 1918, the subject now under consideration was again debated by interested hydraulic engineers, the present writer among the number; and the status of the whole question was summed up by F. P. Stearns, *Mem.Am.Soc.C.E.*, himself an experimenter on weirs of more than 40 years' experience, when he said with startling, yet righteous, precision that "in the present state of the art the weir is not an accurate instrument for the measurement of water."

#### AN ADVANCE IN THE STATE OF THE ART BELIEVED TO HAVE BEEN NOW ATTAINED

After this survey of the state of the art, and to give a résumé of what this article will endeavor to establish, it may not be improper to say at once that it treats of a weir whose discharge is represented by a straight-line formula from 0 up to 9.55 cu. ft. per sec. per ft. in length of weir, and thus continuing, presumably, indefinitely beyond that quantity. Its equation is  $Q = 5.50d$ ;  $d$  being the difference of two observations of water height or pressure; the one taken just upstream from the weir (taken so as to

and others have thought that to attempt to set up a standard form of weir for measuring water was visionary, in view of the many variations in weir discharge so easily brought about. But this very thing was one of the objects of the experiments now under consideration, and time alone will tell whether or no it has not after all been accomplished.

#### THE POWER TEST CODE COMMITTEE OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, AND ENGINEERING FOUNDATION

After this much said in anticipation, we will go back now to a chronological order of events. The American Society of Mechanical Engineers, having appointed a Committee to draft a revised form of Power Test Code in 1917, and invited the three other Founder Societies to appoint advisory committees to the same end, the writer was appointed as one such advisory member. It thereupon very soon appeared that the matter of weir measurements and of their accuracy was in a most deplorable state of confusion. On the proper representations having been made to Engineering Foundation that a new set of experiments on weir discharge were liable to lead to a considerable advance in knowledge in this branch of applied science, it made an appropriation for that purpose, to be expended by the writer.<sup>1</sup> The experiments about to be described have been the result of these preliminaries.

<sup>1</sup> Acknowledgment is also here gratefully made to the President and Faculty of the Massachusetts Institute of Technology, especially to Prof. Edward F. Miller; to Wm. F. Uhl, E. S. Rose and H. L. Woodruff of the office of Chas. T. Main and to Mr. Main; to Chas. W. Sherman, H. P. Eddy, Jr., and others of the office of Metcalf & Eddy and to their principals, all of Boston; and to Builders Iron Foundry, of Providence, R. I., for most efficient aid rendered in various ways at various stages in the conduct of the experiments herein described; and done in a way that amounted to a contribution to enable all the described work to be done.

THE HYDRAULIC LABORATORY OF THE MASSACHUSETTS INSTITUTE  
OF TECHNOLOGY

The place selected for conducting the experiments was the Hydraulic Laboratory of the Massachusetts Institute of Technology. This laboratory had barely been completed when the United States entered the World War, and all the energies of the Institute thenceforth had been devoted to its notable war work to a degree that left improvement in and perfection of its school apparatus rightfully a secondary consideration. As a consequence, the hydraulic part of the laboratory on closer study was shown to have many remediable defects, which, no doubt, will be eliminated in course of time. These, again, affected both the difficulty of making the contemplated experiments and the precision at which results could be attained. But the choice had been made, many reasons existed for persevering in the place where the work had been planned, and thus the experiments were completed as they had been projected.

For a description of the Institute Hydraulic Laboratory refer-

scale of these manometers was based on a coefficient of discharge for the meters of 0.99. These were the facilities at hand, or readily procurable and installable; and though not so precise as a tank measurement would have been, were sufficiently so for the pioneer work to be done. It is not often, as yet, that one can get a reservoir to hold 46 cu. ft. per sec. for the period of a hydraulic experiment; and in the opinion of the writer the venturi meter is the next best thing. It certainly was at the hydraulic laboratory that had been selected for making the present experiments.

That the venturi meter is of a high order of accuracy has been shown by a compilation by the writer for the Power Test Code Committee of all attainable relevant experiments made with it during its existence of 30-odd years. A very significant series of tests, made by F. H. Shaw, Mem.Am.Soc.C.E. of a meter at Lancaster, Pa., show an average variation of 0.036 of 1 per cent for 44 tests covering a period of eight years.

To return to our present meter observations: The scale of the manometers read tenths of cubic feet per second; and hundredths could readily be estimated on both of the meters used.

FIG. 2 THE NEW WEIR (THE SURFACE CURVE OF WATER DISCHARGING OVER THE WEIR IS DRAWN FROM MEASUREMENT.)

ence is made to an account in the March, 1918, number of the *Journal of the Boston Society of Civil Engineers*, by Prof. Geo. E. Russell of the Institute. Briefly stated, the apparatus used in the present experiments and shown diagrammatically in Fig. 1 consisted of a 350-hp. Ball angle-compound engine, 240 r.p.m., direct-connected to a 30-in. Worthington centrifugal pump, having some 48 cu. ft. per sec. maximum capacity at 40 to 45 ft. lift. This pump takes its suction from a system of canals under the floor of the basement, which are or may be connected with the Charles River Basin.

Right here arose one great obstacle in the making of these hydraulic experiments. The canals that have been named at times took to "surging," causing oscillations of the pump-well surface, and these, in turn, were transmitted through the pump and could plainly be seen at the upstream end of the discharge pipe. They were also indicated by the 30-in. venturi meter set in line of the discharge pipe, next downstream from the pump. Two whole afternoons' work were rendered useless from this cause. But by experience and careful work any gross effect from this cause could be avoided.

The discharge pipe delivered into a riveted trough of steel, 5 ft. by 5 ft. and about 135 ft. long, at some 40 ft. higher elevation than the pump. In it was set the 16-in. by 5½-in. venturi meter used to measure quantities smaller than about 8 cu. ft. per sec. (Sept. 25, 26 and 29), the larger quantities being measured by the 30-in. meter already spoken of.

Both these meters were read by means of mercury straight-tube manometers, as made by the builders of the meters. The

From the 5-ft. trough the water fell into a vertical flume or wheel pit 12 ft. in diameter, made of riveted steel and 22.5 ft. high; and through a wooden adjustable flap valve in the floor of this flume, fell into a concrete tail-race pit, which, through racks and gridiron-valve gates, discharged into the concrete channel about 72 ft. long that led to the weir to be tested. The discharge of the weir fell back into the system of canals which fed the centrifugal pump, thus completing the cycle actuated by the Ball engine and pump.

The free discharge of the 5-ft. trough into the 12-ft. vertical flume could be rendered somewhat less turbulent by keeping the flume-water elevation as high as possible without waste, this again being crudely controllable by means of the wooden flap valve in the floor of the vertical flume. But this whole arrangement and the free discharge through the flap valve into the tail-race pit below were imperfect arrangements, acknowledgedly only temporary in character, and were the cause, together with the "surging" of the pump-well water above referred to, of many of the difficulties experienced in making these experiments. They also were the principal cause of most of the lack of precision that remains and is inherent in the final results.

It would have been gratifying to remove some or all of these crudities, and also to greatly extend the scope of the experiments, but the limits of the appropriation available forbade going beyond the work that was actually done.

To vary the discharge, the pump operating at a uniform speed as governed by a flywheel governor, and the boiler pressure also being fairly constant, a throttle valve in line of the pump dis-

charge pipe was used. When the small 16-in. meter set in the 5-ft. trough was in action, the quantity and constancy of the flow leading to the meter and the efficient action of the pump, in spite of the small quantities lifted, could be regulated by opening a waste valve out of the pump discharge pipe. To a minute extent, certainly sufficiently to remove all air from the pump discharge pipe before it reached the 30-in. meter, the same office was performed by keeping in action a 2-in. steam siphon, set at the extreme upstream end of the pump discharge pipe and ordinarily used to exhaust air from the pump before starting it.

The concrete channel above referred to was nominally and almost exactly 10 ft. wide, and had at its downstream end a sharp-crested weir whose crest was about 5.35 ft. above the bottom of the channel. The new form of weir was so designed that it could be built over and around the old weir, and again removed without injury or displacement of what was found on the premises, and with its crest at nearly the same elevation above the bottom of the concrete flume.

#### THE NEW WEIR

In its general outlines, the new weir, Fig. 2, was described in the *Engineering News* 1898 article above referred to. More particularly was it forecast in the Trans.-Am. Soc. C.E. discussion of 1915 that has been named. So here was a case of an invention, or vision, if one pleases, in practical hydraulics that had to wait 20 years in the brain of the engineer for lack of public or private facilities to test it. An attempt to experiment as has now been done was made some 10 years ago, but was frustrated by the writer being informed by the manager of a richly endowed institution that its funds were only available for research in sciences that had no practical applications. The wonder is that any progress at all is made in this most useful of the arts. One endowment only exists as yet for the development specifically of applied science or engineering—the Engineering Foundation, begun by Ambrose Swasey, of Cleveland, Ohio; and it was most gratifying to the writer to have been allowed to endeavor to illustrate some of the work of which such an endowment is capable.

The fundamental idea followed in the design of the new weir was to have the water to be measured conducted over the weir in a gentle manner, and so to have it flow smoothly and regularly from the time it first encounters the weir construction until it leaves it. Instead of allowing the body of water to impinge with more or less violence, according to the velocity with which it approaches the weir, against a perpendicular wall in its path (the upstream face of the ordinary weir) it is gently led to the crest by a 2:1 slope. Instead of striking or being torn over a sharp edge at the crest, the crest is made in the form of the arc of a circle; and instead of bothering about air under the nappe, the nappe is supported on

another 2:1 slope downstream from the crest. Moreover, the crest is made hollow, so that observations of the pressure, or lack of full pressure, whichever the water may elect to exercise, can be taken at the crest, not at a distance upstream from the crest varying according to the fancy of the experimenter.

If the quantity passing the weir turns out to be a function of this observed pressure, well and good. If not, we will see what virtue there is in the difference of water elevations or pressures, the one taken upstream from the weir and the other taken by means of the hollow weir crest.

The difference referred to proved to be the sought-for solution of the problem at hand, and hereafter it alone will be closely considered. A United States patent has been applied for, covering the weir construction herein described.

The orifice in the side of the concrete flume conducting water to the hook-gage pail for measuring water elevations upstream from the weir was made flush with the flume side, at a point 13.9 ft. upstream from the weir crest center, and 1.68 ft. below it in elevation.

Furthermore, to connect the water passing over the weir with the hollow of the weir crest, a series of  $\frac{1}{8}$ -in. holes were carefully bored through into the latter. This was done by first tapping in a solid brass plug, and then boring a hole  $\frac{1}{8}$  in. in diameter through this plug. A natural inclination would be to bore these holes at right angles to the surface curve of the water, but as this varies with the quantity passing the weir, such an inclination is impracticable. There are only two other natural directions for such piezometer holes—either vertical, or at right angles to the upstream slope of the weir; and if the latter, naturally

at the line of tangency of that upstream slope and the arc of the weir crest. The vertical holes are called "Orifices No. 1" and those perpendicular to the 2:1 slope, "Orifices No. 2". The original intention of the writer had been to make the crest tube so that it could be revolved around its horizontal axis, and thus find the best position of the piezometer orifices, but a cumbersome and unduly expensive experiment like this was at once abandoned, and in view of the success already attained, may now be disregarded by engineers.

Both kinds of piezometric orifices were tried, and the last-named proved much the superior for general use.

To vary the velocity of approach a false bottom was put into the channel for some of the experiments. These will be designated as having been made with "reduced depth" and others with "full depth."

The diagrammatic drawing, Fig. 1, will make clear the description of the weir test apparatus given in the foregoing paragraphs.

To increase the quantity per foot in length of weir, the avail-

FIG. 3 THE SHARP WEIR IN ACTION

Leakage on each side could be measured either by the new formula; or by catching it in a pail and weighing the amount caught in an observed period of time; or by both these methods simultaneously.

able capacity of the pump was in many of the experiments made to pass over only about 3.3 ft. of the length of weir, as shown in Fig. 3, while other series of the experiments used a weir about 10 ft. long.

As these experiments had a practically useful end and aim—the establishing of a commendable method of weir measurements—end contractions were ruled out from the very beginning. They are of no use, ordinarily, and only complicate the situation. Even in the few cases of working with sharp-crested weirs, when side contractions are introduced so as to cause greater depths upon the weir with a diminishing quantity of water, or so as to cause a selected formula to apply, they could be avoided at the cost of a very little extra carpenter work. But with the straight-line formula about to be established and valid from zero up to the maximum found by the experiments herein described, there is no occasion whatever to change the length of the weir so as to accommodate the quantity of water about to pass it, and side contractions become either foolish or pseudo-scientific. None of the following experiments includes them.

FIG. 4 APPARATUS TO OBSERVE THE WATER ELEVATION UPSTREAM FROM THE WEIR, AUTOMATICALLY CORRECTED FOR "VELOCITY OF APPROACH"

#### AUTOMATIC CORRECTION FOR VELOCITY OF APPROACH

In the photographic view of the new weir in action, Fig. 3, a vertical brass pipe dipping into the water will be noticed in the background, which is also shown in detail in Figs. 4 and 5. This was intended as a means of observing the water elevation upstream from any part of the weir, automatically corrected for velocity of approach, by taking in the water pressure through a pitot orifice pointing upstream and transmitting it to a hook-gage pail in the usual manner from out of the downstream side of the vertical tube. A pointer above water, parallel to the pitot tubular orifice, which should point upstream, insures its correct position. Our experience leads us to advise that the vertical tube be not used as a reservoir, but only as a support for the pitot orifice.

The tube is held in its guides by two clamp screws, and may readily be set so as to bring the pitot orifice in the locus of mean velocity as it may be judged or found. In these experiments it was set at 6/10 depth of water, and  $\frac{1}{2}$  the width of the channel from either side. A scale of feet and tenths on the tube, reading up from zero at the pitot orifice, and aided by another scale or gage painted on the side of the concrete flume, reading up from zero at the flume bottom, readily permitted this. The apparatus is mounted on two beams crossing the water channel and at a convenient height above it.

This apparatus exists as yet only in theory and should be experimented with at the first favorable opportunity, because on drawing the water out of the flume at the close of our experiments a broken and leaky joint was discovered in the rubber pipe that carried the water pressure from the vertical tube to the hook-gage pail, so that the readings taken proved unreliable, or of no record value whatever.

#### NEED AND SCOPE OF FURTHER EXPERIMENTS

A crew of six men, including three observers, with a captain, had been working with the apparatus from September 10 to October 3, 1919, and it was with great regret that the writer gave the order to dismantle the weir because so much remained to be discovered.

But October 3 was Friday, the last day of the week for us. The laboratory closed at 5 p.m., and on Monday the regular school term commenced. The appropriation for the work was high exhausted and it was high time we quitted the premises.

FIG. 5 DETAILS OF APPARATUS SHOWN IN FIG. 4 TO OBSERVE THE WATER ELEVATION UPSTREAM FROM THE WEIR

There was, first of all requiring further investigation, the effect of the radius of the weir crest. Bazin had experimented on a weir composed of two 2:1 slopes meeting at a sharp angle and with a little pipe to indicate pressure "under the nappe," *let into the body of the weir slope upstream from the crest.* This can not enlighten us very much, but is the nearest approach to our experiments known to the writer.

Our weir crest had a radius of 0.198 ft., and the outside surface was hard and smooth oil paint.

No doubt the radius of the weir crest is a factor in the application of the formula found for weirs of the construction shown in this article, but it remains for other sets of experiments to reveal the limits and detailed effects of this radius.

#### THE EXPERIMENTS

With these preliminary statements, the record of the 40 experiments made is given in Table 1. Four of them have been marked doubtful on account of actual or supposedly defective observations and all those made September 9 and 30, also part of those on September 25, had to be rejected as worthless on account of the previously mentioned violent "surging" of the water discharged by the pump.

A separate set of gagings was made October 3 to compare the indications of the Institute's sharp-edged weir with the Institute's 30-in. venturi meter. Owing to the fact that this meter is set in line of the pump discharge pipe, only 12 ft. distant from the pump, it had been a question whether at that short range it would meter accurately, and the experiments of

FIG. 6. DIAGRAM SHOWING THE RESULTS OF THE 40 EXPERIMENTS MADE

October 3 were made for the purpose of answering this question. The system for observing head on the weir, available, was that known as the Feley and Stearns method. A metal plate was set in the side of the concrete flume, flush with it, and an orifice in this plate in the present instance was situated 6.8 ft. upstream from the crest and 1.68 ft. below it in elevation, connected with a hook-gage pail in the usual manner.

#### RECORD

Pump started about 12.30 p. m., discharging 30 cu. ft. per sec. at 1 p. m. All quantities corrected for velocity of approach.

	WEIR	METER

<sup>4</sup> Short weir, reduced depth.

<sup>5</sup> Short weir, reduced depth, No. 2 orifices.

<sup>6</sup> Short weir, full depth.

trough, 12-ft. vertical flume, wooden flap valve, into the 10-ft. concrete flume, and over the weir, as already mentioned, it is quite possible that 38.13, 30.33, 17.91 and 11.73 cu. ft. per sec. were passing the weir on the average for 5 min., while 38.30, 31.25, 18.80 and 11.00 cu. ft. per sec. were being discharged by the pump on the average during the same 5 min. The difference could very well represent rise or fall in the mean elevations of the water in either the 5-ft. trough, the 12-ft. vertical flume, or in the 10-ft. concrete flume, or in two or more of these containers simultaneously.

The comparison which was made, alone, does not argue for superior exactness of gaging by either the weir or the meter—that must be determined by tank tests made with the two separately. It only showed that neither was materially inexact. And we know from data that have been given, that next to tank tests the venturi meter is an exact method for measuring water.

And with the result placed in evidence, that No. 2 orifices act according to the straight-line equation—

$$Q = 5.50d \text{ in English units}$$

$$Q = 1.675d \text{ in metric units}$$

this paper might fitly close.

The Long-Range Gun in Action

## The German Long-Range Gun

An Account of the German Super-Gun Bombardment of Paris from the Forest of Gobain, 70 Miles Distant, in the Spring of 1918. Together with Authentic Details Regarding the Design of the Gun, Carriage, Emplacement and Projectile

By LIEUT.-COL. H. W. MILLER, U. S. A.

AT 7.15 on the morning of March 23, 1918, just two days after the Germans opened their offensive against the British 5th Army before Amiens, the people of Paris were startled by an explosion of something that had fallen on the Quai de Seine. The explosion was of such magnitude that it could be heard over practically the whole of Paris. Fifteen minutes later there was another explosion of the same magnitude, but this time closer to the Seine, on the Rue Charles V; fifteen minutes later another explosion occurred on the Boulevard de Strasbourg near the Gare de l'Est. Until that time Paris had never been bombarded except from airplanes and zeppelins, and the first thought of the people was that they were being bombarded from some new type of aircraft that was being operated at such a height that it was practically invisible.

The explosions continued to occur throughout the morning at very uniform intervals of 15 min., and by evening 21 explosions had occurred at the places shown in Fig. 1. After the first few explosions, between seven and eight o'clock in the morning, business in Paris practically ceased. Stores were closed and part of the Metro system ceased to operate; ticket offices in some of the railway stations were closed, and great numbers of people could be seen walking the streets looking skyward trying to locate the planes that were dropping the supposed bombs.

### THE BOMBARDMENT OF PARIS

Information of the extraordinary bombardment was telephoned and telegraphed over practically the whole of France within a few hours and was received everywhere with amazement. After a few hours of the first day a sufficient number of the fragments

of the exploding agent were collected by officials in Paris to identify it as a projectile being fired from a gun, rather than a bomb being dropped from an airplane. By noon representatives of the Heavy Artillery Section of the Ordnance Department, located at Tours, had made preliminary calculations in response to telephone instructions from Paris giving the probable muzzle velocity at which a projectile would have to start in order that it might travel from a few kilometers within a point of the German lines nearest Paris to the center of Paris. Inquiries were made likewise of the Section as to the possibility that these projectiles could actually be coming from a gun within the German lines. The reply was that the probable muzzle velocity of the projectile, if it was actually being fired within the German lines, was not less than 4500 ft. per sec. No such muzzle velocity had, to their knowledge, ever been realized, but with a gun of sufficient length and with a powder burning at a satisfactorily low speed it was considered quite possible for the projectiles to be fired from within the German lines. By the end of the first day officers of the French, as well as the American, armies were quite certain that the projectiles were being fired from a newly designed long-range gun located within the German lines, and operating at a probable range of 110 km. (68.8 miles).

During the next few days some interesting theories were advanced in the various newspapers. In one case it was maintained that the projectiles which arrived in Paris were being fired from another much larger projectile, which actually served as a gun. This larger projectile was said to have been fired from a gun within the German lines, and upon attaining a certain height a charge of powder within the larger projectile was automatically ignited, firing the smaller one to a much greater distance. The theory that the projectiles were being fired from guns concealed in abandoned quarries or in heavily wooded regions near Paris received considerable credence, and diligent search was made of

<sup>1</sup> Office of Chief of Ordnance, Artillery Division, Washington, D. C.  
Released for publication by the War Department, Office of the Chief of Ordnance, and contributed to MECHANICAL ENGINEERING.

all such places to be certain that it was not true. A third theory was that the projectiles were being fired from a pneumatic gun located within Paris.

A plotting of all the bursts for the first day showed results that were very puzzling. If the guns were being operated at comparatively short distances, the only way to account for the tremendous dispersion was on a basis of actual laying of the gun for different objectives. This theory did not seem plausible, however, because if the gun was actually laid on given objectives, these objectives were of relatively small importance. If, on the other hand, the projectiles were being fired from a gun at a great distance, it was

FIG. 1 MAP OF THE CITY OF PARIS, SHOWING POINTS OF BURSTS ON FIRST DAY OF LONG-RANGE BOMBARDMENT (MAR. 23, 1918) IN THE ORDER OF THEIR ARRIVAL

FIG. 2 MAP OF THE CITY OF PARIS, SHOWING POINTS OF BURSTS ON LAST DAY OF THE LONG-RANGE BOMBARDMENT (AUG. 5, 1918) IN THE ORDER OF THEIR ARRIVAL

seen at once that the dispersion was so great as to make it practically impossible to hit with any certainty any objective much smaller than that portion of Paris within the walls. It was noticed that the dispersion in direction, that is, to the right or to the left of the line on which the projectiles were arriving, was comparatively small, while the dispersion in range, that is, over or under the probable point at which the projectiles were supposed to arrive, was very great. Examination of the map, Fig. 1, shows that on this first day, when the gun was new, the average dispersion in range was very small compared with the dispersion on later days when the gun became worn.

Evidence received later indicates that at the end of this first day's bombardment the first gun was about half worn out.

Eighteen projectiles had fallen within the walls of Paris, and three outside; fifteen people had been killed and thirty-six wounded. The destruction of property had been comparatively small. By "comparatively" it is meant that the destruction was small in comparison with that wrought by the 100- and 300-kg. airplane bombs. Whenever the projectiles landed in the street or in an open plot of ground, the hole made was seldom more than from 12 to 15 ft. in diameter, and from 4 to 6 ft. in depth. When the projectiles struck buildings it was not unusual to have them explode in the interior without showing any serious signs of damage on the outside.

On the 24th of March thirteen projectiles fell within the walls of Paris and nine without, killing eleven people and wounding thirty-four. On the 25th, four projectiles fell within the city and two without. This was the end of the first gun. It was worn out, and no more firing was done until the 29th, when the second gun began its work.

Search of the files of the French War Office revealed the fact that full drawings and plans had been on hand for quite a long time for such a gun as the Germans were probably using. These specifications had been submitted a number of years before and had been discarded because of the excessive expense and the tremendous difficulties involved in manufacturing such a gun. It was considered likewise by those who had turned down the speci-

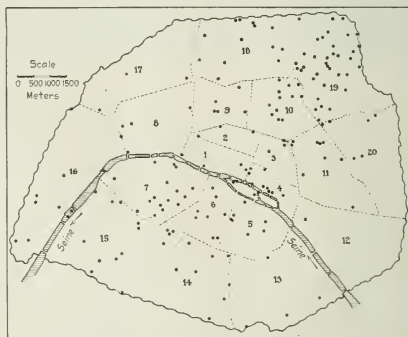

FIG. 3 MAP OF THE CITY OF PARIS, SHOWING POINTS OF BURSTS OF THE 183 PROJECTILES THAT FELL WITHIN THE WALLS IN 44 DAYS OF BOMBARDMENT

cations that the value of such a gun was extremely questionable. It was realized that its dispersion would be excessive, and that with the powders with which the service was then familiar it would be exceedingly difficult to secure a muzzle velocity sufficiently uniform to do effective work.

#### DETAILS OF THE BOMBARDMENT

When the bombardment was over an examination of the periods over which it had extended indicated that it had been divided into three distinct series. The first extended from March 23 to May 1; the second from May 27 to June 11, and the third from July 15 to August 9. It seems certain that this division into series was a part of the plan of the large offensives being waged during that time. Table 1 on page 99 gives the bombardment by days during this entire period and shows the number of projectiles falling within and without the walls of Paris each day, and the number of people killed and wounded. During the first few days of the bombardment the first projectiles arrived between seven and eight o'clock in the morning and continued to fall at intervals of 15 min. through a portion of the day. On later days the bombardment would begin at 12.40 noon.

Much has been said with reference to the effect of this bombardment on the people of the city of Paris. The writer's first direct acquaintance with the bombardment was during the third and fifth days. With considerable surprise it was observed that already the people were taking it quite philosophically; in fact, it could not be seen that they were paying much attention to it at all. At intervals of about fifteen minutes muffled explosions would be heard in different parts of the city, seldom two consecutive explosions in the same vicinity. Many people would stop for an instant and attempt to decide from what direction the sound had come, after which they would go on their way apparently unconcerned. It was, of course, still sufficiently novel to be of considerable interest, and people were talking about it everywhere. It is quite probable that the regularity with which the projectiles were arriving got on the nerves of some people, and that the bombardment was responsible for the departure of some of those who

the population left the capital and so increased the alarm caused by our successes." He is right, the bombardment did make a great impression; it made every one more angry, and alarmed very few. It is certain now that they could ill afford to use their manufacturing facilities for the making of such guns as these at a time when they were so desperately in need of heavy field guns to assist their armies in their big drives.

Long-range or super guns received consideration from the Allies for a very short period. There was a tendency at the time to favor construction of a great number of them, but a saner view soon prevailed and actual steps were taken for the construction of only a very few. Both the British and the French Governments began the construction of a limited number, some of which have now been finished. They built them, however, with a clear understanding that they could hope for but little more from them than the Germans were getting from their own. American ord-

FIG. 4 DETAILS OF DESIGN OF THE GERMAN SUPER GUN (DIMENSIONS IN METERS)

were crowding the trains west and south from Paris. It seems more certain, however, that by the first of June the close proximity of the Germans to the city of Paris, together with the anxiety caused by another drive impending, added to the effect of the heavy bombardments from airplanes on every clear night, had far more effect than the gun. The visible destruction of property was so slight as to give little evidence to any one traveling about the city that the explosions they were hearing from time to time amounted to anything. The newspapers were very careful to avoid any discussion or even a lengthy reference to the bombardment from day to day, and neither gave the locations of the places where the projectiles had fallen nor the number of killed or wounded.

The Germans must certainly have known that their gun was not a profitable investment for the destruction of property, hence they must have continued the bombardment purely for its destructive effect on the morale of the Parisians and its beneficial effect on the morale of the Germans. This is likely the purpose which prompted the construction of the guns. In his book, *My Thoughts and Actions*, General Ludendorff says: "During the battle we had commenced bombarding Paris from near Laon with a gun having a range of 75 miles. This gun was a marvelous product of technical skill and science; a masterpiece of the firm of Krupp and its director, Rausenberger. The bombardment made a great impression on Paris, and on all France. Part of

nance officials feel that it would not profit us to construct more than two or three such guns at the very most, and probably none at all.

Within a very few days from the beginning of the bombardment it was possible, through careful examination of the direction of the passage of the projectiles through various buildings, to determine quite accurately the direction of their arrival and the probable place from which they were coming. This place was in the Forest of Gobain, southwest of Laon. Very soon thereafter the French Air Service was able to locate in this same forest three positions from any one of which, or possibly from all of which, the guns were being operated. Only one of these was sufficiently close to the German and the Allied lines to permit of any possibility of operating against it with the heavy guns then in service. The gun selected was a 34-cm., 45-caliber French gun on a railway mount. This mount was run up to a point very close to the lines and behind a hill of such size as to effectively conceal it from German line observers. It was well camouflaged by nets against the air observer and against German sound-ranging apparatus by placing two smaller guns at the right and left and several hundred yards behind it. These smaller guns were fired at intervals of one and two seconds before the larger gun, and evidently had the effect of so disturbing the German sound-ranging apparatus as to make it impossible to locate the heavy gun. After a half-day's firing from the 34-cm. gun, air photo-

Ordnance Works at Pilsen in Austria. During the period of active warfare many reports were received with reference to the design of the gun, but never any information with reference to the carriage. The various reports on the gun agreed quite closely in the essential details.

In May 1919 a commission of ordnance officers was sent to the Skoda Works in Austria for the purpose of investigating their methods of constructing large and small ordnance. While there they secured additional data from the chief engineer of the plant with reference to the design of the gun, and saw the three guns which had been in process of construction on November 11, 1918. This engineer stated that when the first German gun began to fire on Paris, it was as much a surprise to the Austrians as it was to the Allies. Shortly thereafter he went to France to examine the gun and observed it in action. It was not until a few months before the armistice that the three guns were sent to Pilsen for conversion into long-range guns. Evidently the Germans had considered the bombardment a success, or sufficiently so to warrant the use of manufacturing facilities for the construction of a greater number of guns than they were able to handle at the Krupp Works at Essen.

The details of the design of the carriage for the gun were not learned until April 1919, although it had been quite certain since August 1918 that the emplacement found southwest of Fere-en-Tardenois was intended for the carriage of the long-range gun. Until July 1, 1919, no direct information had been received from the Germans with reference to the design of any part of the entire

### THE GUN

All of the long-range guns were constructed from worn-out 38-cm. (15-in.) 45-caliber (17.1 m. or 56 ft. in length) naval guns. The converted gun was in two parts, the main section 30 m. or 98.5 ft. in length, and the forward section 6 m. or 19.7 ft. in length. The 38-cm. gun was bored out and a very heavy tube with an inside diameter of 21 cm. was inserted, Fig. 4; 12.9 m. or 40.23 ft. projected beyond the end of the original gun, and over this projecting portion another hoop was shrunk and locked to the forward hoop of the old gun. This 21-cm. tube was rifled at an uni-

FIG. 9 PLAN OF ELEVATING MECHANISM

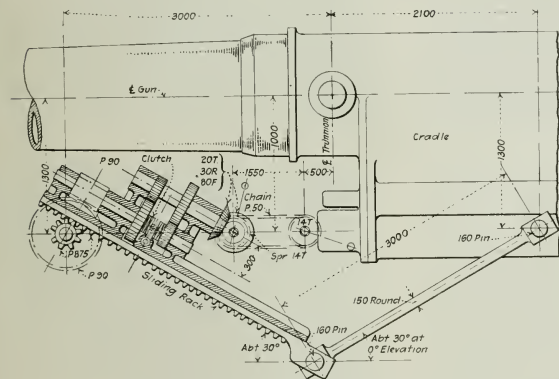

FIG. 8 SIDE ELEVATION OF ELEVATING MECHANISM

mechanism except the gun on which, as mentioned before, information had been received at various times before the armistice; the guns themselves were examined at the Skoda Works at Pilsen. Just why the Germans refused to talk about this gun is not known. In December 1918 and January and February 1919 a German engineer who was working with the American forces in the region northeast of Verdun helping identify long-delay fuses and assisting on other technical matters said that he was acquainted with the design of the gun and had seen it in operation. Very curiously, however, he refused to give any information with reference to the details of the design and was quite positive in his assertions that the Allies would never see any of the guns, and certainly not any of the carriages. This was difficult to understand in view of his perfect willingness to talk about the details of design of any other piece of ordnance that he was at any time asked about, and it was more curious in view of the fact that there is really nothing wonderful about the design of the long-range gun, its carriage or its emplacement.

form twist throughout its length. The other section, 6 m. in length, was attached by means of an interrupted thread and heavy outside collars or flanges. This section was unrifled and was of an inside diameter equal to 21 cm. plus twice the depth of the grooves in the rifled section. It was assembled to the gun in the field and not removed until the gun had been worn out. The total weight of the original 38-cm. gun was 152,550 lb., and the weight of the reconstructed gun approximately 318,000 lb. The 21-cm. liner was of such thickness that on being worn out at this caliber it could be rebored first to 24 cm. (9.3 in.) and later to 26 cm. (9.93 in.). Its probable life at any one caliber was not more than 50 rounds, and the maximum powder pressure did not exceed 3000 atmospheres or 44,000 lb. per sq. in. The design of the breech mechanism of the original 38-cm. gun did not require modification.

The long-range guns constructed by the British and French governments do not follow the German design to the extent of having a smooth-bore section on the front. The purpose of this feature was for some time in doubt and is worthy of some discussion.

The gun just described is approximately three meters longer than either the British or French long-range guns, both of which are rifled throughout their length. Two reasons might be given for the extra section.

Possibly additional linear velocity was imparted to the projectile as it traveled through the 6-m. smooth-bore section. It seems improbable, however, that this could be its primary purpose, inasmuch as the muzzle velocity was such a variable quantity. It is more probable that its purpose was to align the axis of the projectile more perfectly with the axis of the bore of the gun and reduce to a minimum the angular velocity of yaw as the projectile left the muzzle. When it is understood that this projectile was to mount to a height of about 24 miles and travel a horizontal distance of 76 miles, it can easily be appreciated that any tendency that the projectile might have to throw its axis out of alignment

FIG. 10 THE GUN CARRIAGE. (THE GUN SHOWN IS THE 38-CM. 45-CALIBER GUN FROM WHICH THE LONG-RANGE GUNS WERE MADE)

with its theoretical path would have disastrous results. Through the impracticability of making projectiles fit perfectly in a gun they have a tendency to hammer the walls as they travel down the bore. This hammering action of the projectile is the result of the operation of two forces, the one tending to increase its linear velocity and the other to increase its rotational velocity. The latter force is acting only while it is traveling through the rifled section. It is invariably true that just as the projectile is leaving the ordinary gun it is on on- of its up, down or crosswise hammer strokes, and that the axis has a tendency to yaw or deviate from its theoretical path at a certain angular velocity. Card-board screens placed in front of guns in proof firing invariably show elongated holes, and not infrequently very decidedly so, even at no greater distances than 100 ft. from the muzzle. This tendency to yaw has a detrimental effect on the accuracy of even our comparatively short-range guns, but no effective means have yet been devised to neutralize it. With the extreme-range gun it is so much more serious that it seems quite likely that the Germans adopted this method of neutralizing it, thereby reducing the dispersion both in range and in direction. It is not improbable that the German gun was first constructed without the smooth-bore section, and that its shooting was found to be so erratic as to require the addition of this feature.

This gun was operated at a muzzle velocity of from 1500 m. (4760 ft.) to 1600 m. (5090 ft.) per sec. and at an elevation of 55 deg. This 55 deg. is worthy of comment, inasmuch as it has ordinarily been supposed that nothing could be gained in range by elevating a gun above 45 deg. It is known, of course, that if a projectile is fired in a vacuum its maximum range is attained when it starts at an elevation of 45 deg. When fired in the air, however, the initial angle which permits it to attain its maximum range depends both on the caliber and weight of the projectile and the velocity at which it leaves the gun. With reasonably large and well-designed projectiles, it may be said that for each muzzle velocity (a) there is a density of air (b) into which the projectile should enter at an approximate elevation of 45 deg. For this projectile and the muzzle velocity of 1500 m. per sec. the initial elevation of the projectile is 55 deg. It is very doubtful whether any additional range can be secured with any projectile at any muzzle velocity at an elevation above 55 deg.

Attention was called in the discussion of the first day's bombardment to the tremendous dispersion in range. Some of the

projectiles fell just within the wall at the northeast side of Paris, and some within the walls at the southwest side. This is accounted for by the fact just mentioned that the muzzle velocity of the projectile varied as much as 100 m. per sec. It was impossible with the powder that the Germans were using to secure a muzzle velocity with a variation of less than 100 m. per sec.

#### THE GUN CARRIAGE

**Cradle.** The cradle, Fig. 5, is a cylinder of simple design having ribs at long intervals and of a depth of only about 3 cm. The walls of the cylinder have a minimum thickness of 10 cm. and a maximum thickness of 13 cm. over the ribs. The diameter of the main trunnion is 46 cm. and the length 33.5 cm. A collapsible counterweight is attached to the top of the cradle.

In firing, the two sections of this counterweight are raised and locked together for the purpose of raising the center of gravity

to such an extent that the gun may be elevated and depressed more easily. This cradle is of a naval design, the front section being so shaped as to close the opening in a turret. It is not improbable that the cradle as well as most of the 38-cm. guns were removed from German ships or coast fortifications.

**Recoil Mechanism.** The recoil mechanism is composed of two hydraulic recoil cylinders and one spring-pneumatic recuperator cylinder, all attached to the bottom of the cradle, Figs. 6 and 7.

FIG. 11 GIRDER DETAILS

Each of the recoil cylinders is a separate cylinder carried in brackets cast on the cradle, and each is provided with a buffer approximately 32 cm. long. The plugs through which the cylinders are filled are on the ends of the buffers. The approximate length of recoil is 1.3 m. (50.5 in.). This distance is, of course, approximate and was arrived at after careful examination of the cradle. A report examined in the office of the Chief of Artillery of the Belgian Army at Brussels gives the length of recoil as 1.15 m. Inquiry disclosed the fact that this length of recoil was also approximate.

Two rods *a, a*, screwed to the recoil lug of the gun, Fig. 6, and extending to the rear, carry a heavy crosshead *b* to which the

FIG. 13 SIDE VIEW, RECUPERATOR PUMP AND BREECH MECHANISM

FIG. 15 ANOTHER VIEW OF EMPLACEMENT SHOWN IN FIG. 14

FIG. 12 DETAILS OF GUN CARRIAGE

FIG. 14 EMPLACEMENT (BOIS DU CHATELET)

piston of the recuperator cylinder is attached. The recuperator cylinder is likewise a separate cylinder carried in brackets cast on the cradle. At the rear on both sides it is planned to serve as a guide for the recoil lug to prevent rotation of the gun.

**Elevating Mechanism.** The elevating mechanism of this mount is extremely heavy and unique in design. The cradle was evidently originally provided with the screw type of elevating mechanism, the screw being hinged to the cradle at the rear end.

The specification that the gun be provided with an elevation of 55 deg. necessarily led to the discarding of the screw mechanism. The straight racks shown on Fig. 8 slide in ways which are parallel to the inclined lower face of the forward end of the side girders. It was necessary to put them in this position to secure sufficient movement to attain to 55 deg. At the lower end they are connected with each other by a heavy shaft to which are attached the two connecting rods running up to the bottom of the cradle (Fig. 9). Provision is made for two handles on each side of

at the front and rear by heavy structural-steel transoms. They are further reinforced in the front by the heavy cast-steel housing for the elevating gear. The trunnion seats are of cast steel and are simply bolted to the top chord with single key plates at their rear. This single key plate has the positive backing of one top cover plate. The face of the horizontal section of the lower chord of the side girders is planed and is provided with key plates at each end, Fig. 11. Eight 2-in. holes are provided in each lower chord at the front end and six at the rear for bolting the mount to the emplacement.

#### THE ANCHORAGE

When the German Army had retired from the salient between Soissons and Rheims in August 1918, the emplacement shown in Figs. 14 and 15 was found in the Bois du Chatelet, 9 km. directly north of Chateau-Thierry. This emplacement was in process of

FIG. 16 PLAN OF EMPLACEMENT SHOWN IN FIGS. 14 AND 15

the car, each for two men, Fig. 9, and a two-speed transmission is provided, permitting the mechanism to be operated at low or high speed. The ratio of the low-speed gear is  $4\frac{1}{2}$  turns of the handle for each degree of movement of the gun. It was not possible to determine the ratio of the high-speed gear, since the two men making the examination could not operate it. It seems probable, however, that eight men could operate the mechanism at high speed without undue difficulty.

**Traversing Mechanism.** See later paragraphs dealing with the anchorage.

**Railway Car Body.** The railway car body shown in Figs. 10, 11, 12 and 13 is made up of two single-web side girders connected

installation, and had not been completely erected. The Germans attempted to destroy it, but succeeded only in ripping loose a few plates. At the time the emplacement was captured, no description of any kind was available of the carriage for which it was intended. The writer's failure to find any emplacement in Belgium from which the mount examined there could be operated led to further examination of the emplacement in France, and it was found that they fitted perfectly.

The emplacement is in two main sections, one a base and the other a rotating section. The rotating section, which is shown in Figs. 16 and 17, is about 28 ft. 6 in. in diameter and is supported on 112 8-in. steel balls. The base of this section is about 35 ft. in

diameter and 6 ft. in depth. In Fig. 14 there can be seen at right angles to the direction of the track of the rotating section two girders, on the ends of which are key plates or pads. The plate which is labeled has six holes in it, and the plate on the opposite end of the girder has eight.

The mount is run on to the emplacement with the rotating section in the position shown in Fig. 14. It is then raised by the four jacks, which can be seen at the left of Fig. 14, and are shown in their exact positions in Fig. 16. When the mount is raised the trucks are removed and the rotating section of the emplacement turned through 90 deg. On lowering the mount on to the emplacement, the key plates on the bottom chords of the carriage are fitted to the corresponding key plates on the emplacement. The emplacement is shown in process of installation, with the gantry crane still in place, Fig. 19.

The carriage on which the gun is so mounted as to be capable of movement in a vertical plane only is traversed by rotating the top section of the emplacement. A complete circular traversing rack made up of angles and steel pins is bolted to the structural base (page 89). A pinion carried on a vertical shaft on the side of the rotating section which corresponds to the rear of the ear-

mount from the trees on either side, and in Fig. 19 it can be seen that the gantry crane as well as the emplacement, while in the process of installation, were covered with tree branches.

*Trucks.* All of the trucks as well as the span bolsters are constructed entirely of structural steel as shown in Fig. 20. The front trucks contain five axles each, and the rear trucks four axles each. The journals are approximately 14 cm. in diameter by 22 cm. in length. The wheels are 95 cm. in diameter. On the front trucks three wheels are provided with two brakeshoes each; on the rear trucks the end wheels are provided with two shoes each and the inner wheels with one shoe each. The braking is done by hand only. The axles are equalized in pairs only. The center axles of the front trucks have no connection with the others. In Fig. 10 a portion of a circular rail can be seen on the top of the front truck on which the pads attached to the span bolster on each side bear.

#### AMMUNITION SUPPLY SYSTEM

The provisions made for supplying ammunition are shown in Figs. 21, 23, and 25. These same provisions were used for the

FIG. 17 ELEVATION OF EMPLACEMENT SHOWN IN FIGS. 14 AND 15

riage engages with this rack, and the mechanism is driven by two two-man handles on a horizontal shaft carrying a worm engaging with a worm wheel on the top of the vertical shaft, as shown at the right of the top view, Fig. 16. This shaft may likewise be driven by means of the four handles mounted on the two cases in the center of the rotating section and connected with the worm wheel and shaft through two shafts carrying two universal joints each. Apparently the mount was generally traversed by means of these latter handles, if one may judge of the scheme of operation shown in the illustration on page 89.

*Camouflage.* In the case of the emplacement found in the Bois du Chatelet, sockets were placed in the center of the approach track at intervals of about 30 ft., into which trees with trunks up to about 6 in. in diameter could be placed for the purpose of concealing these tracks. In the illustration of the gun in action, page 89, it will be observed that netting has been stretched over the

operation of the 38 cm. 45-caliber naval guns from which the long-range guns were made. The extension to the car body shown in Fig. 21 was used for the operation of the 38-cm. gun under certain conditions. This was not required and was removed when the long-range gun was operated on the carriage. In Fig. 25 a removable plate can be seen between the shot-truck rails. Above this removable plate is a light bridge, in the center of which is seen a ball on the end of the cable used in hoisting projectiles through the hole in the floor. This cable runs over a series of pulleys to a small drum in the box on the top of the left-side girder. The ammunition was supplied from the storehouse over the narrow-gauge track shown in Fig. 23, the circular portion of the track being under the opening in the center of the floor of the mount. The gear in the box on the side girder is of the double-speed variety, the high speed being provided probably for rapid operating in the hoisting of powder.

FIG. 19 EMPLACEMENT IN PROCESS OF INSTALLATION

## AMMUNITION

The projectile used with this gun is shown in Fig. 24. Its weight is 120 kg., or 264 lb. The length of the main portion of the projectile is 490 mm., or approximately 19 in. To this was attached a false ogive or cap, the exact length of which is not known; it was probably as long, if not slightly longer, than the main portion of the projectile. The radius of the curve of this ogive was about 7 calibers or 58 in. The design of the interior as well as the exterior of this projectile is unique in many respects. It will be noted that the charge was separated into two parts by a diaphragm which has a number of holes in it. Two fuses are used, the one in the diaphragm and the other in the base. All of these projectiles were most carefully machined to elaborate specifications in order that the weight and dimensions might be practically exact and the center of gravity perfectly located; even after they were thus machined they were sorted out into lots according to their characteristics by weight, dimensions and location of the center of gravity, and the various lots of projectiles marked with center-punch marks. The necessary corrections in elevation and deflection were calculated for the projectiles of these various lots. The projectiles which fell in Paris were successively marked with three center-punch marks in a triangle or four center-punch marks in a square, etc.—projectiles of the same marking arrived consecutively.

The outside of the projectile was provided with two copper

bands which served as gas checks, and in front of each of these copper bands the projectile was enlarged and rifled for a length of 70 mm. or 2.7 in. The shear from the extreme acceleration necessary to produce the required muzzle velocity was such that the ordinary copper bands could not be made to serve as rotating bands. The shearing strength of the copper is not sufficient to stand the strain that would have been put on the bands with so great an acceleration. The friction between the lands of the gun and the projectile was so great as to wear the gun appreciably on each round fired. This was evident from examination of the copper bands of successive projectiles. As a result of the necessity for providing rifled projectiles, it was necessary in placing

FIG. 20 TRUCK DESIGN

the projectile in the bore of the gun to fit the forward rifled section of the projectile into the beginning of the rifling of the gun, Fig. 4. The exact details of the design of the portion of the tube between the beginning of the rifling and the powder chamber are not known. It seems quite probable, however, that there is a smooth section of about 12 in. into which the portion of the projectile back of the first copper band fits, bringing the base of the projectile to the end of the powder chamber. The fact that the forward rifled section of the projectile was already fitted into the grooves of the gun made it certain that the rifled section at the

<sup>1</sup>Shell struck an arch in the roof of the Church of Saint Gervais. <sup>2</sup>Night and day. <sup>3</sup>Night.

rear would likewise fit as the projectile began to move up the gun. It has been noted before that this projectile departed at a muzzle velocity of from 1500 to 1600 m. per sec. The velocity remaining on its arrival in Paris was approximately 700 m. per sec. and the time of flight about three minutes.

The analyses made of the various parts of the shell are as given in Table 2.

Not a single one of the 303 projectiles that fell in or about Paris failed to detonate. Evidently the two fuses were responsible for this excellent record. The practice of separating the charges into two parts by a diaphragm is not new. The diaphragm had been used before in heavy French projectiles as a guarantee

against the effects of inertia which might either provoke a premature explosion in consequence of the friction of the molecules of the charge against each other or might bring the charge beyond the critical density point, after which it probably would not detonate. At one time a theory was advanced to the effect that this diaphragm separated two liquids which mixed and detonated upon the fall of the projectile. There seems no good reason to believe that this could have been so.

#### PREVIOUS DESIGNS AND LIMITS IN DESIGN

It has been mentioned already that investigation disclosed shortly after the beginning of the bombardment that an almost identical design had been proposed to the French government not

FIG. 21 VIEW SHOWING LOADING GEAR, TRUCKS AND BOLSTER

many years before. Further search of French and English records has brought to light the fact that the rifled projectile is quite old and seems to antedate the copper band considerably. In 1892 Sir Alfred Noble made a 100-caliber 6-in. gun which gave a muzzle velocity of 3700 ft. per sec.; in the same year the French government constructed a 10-cm. 80-caliber gun from which they attained almost the same muzzle velocity. It is not known what range was secured in either case. The forms of most standard projectiles at that time were not such, however, as to make it possible to secure the maximum range from the above-noted velocity.

FIG. 22 BREECH MECHANISM, RECUPERATOR GAGE AND TRAVELING LOCK

In taking up the design of such guns again the French and English services found that with guns of practicable length and muzzle velocities attainable with guns of such length, and with available powders, the projectile that would permit the greatest range to be realized would be approximately 8 in. in diameter and weigh from 225 to 250 lb. An appreciable change up or down in the diameter or the weight of the projectile would result in a loss of range. The gun designed by one of our allies uses a projectile weighing 240 lb. and a powder charge of 350 lb. One of the

to give a uniform pressure through a large portion of the period of the travel of the projectile in the bore of the gun. The powder made by one of our allies for their long-range gun is in flat strips resembling cardboard. These strips are three-ply, the various sections burning at different rates. The large sticks of powder mentioned above for the gun of the other of our allies is special, and is expected to live up to the characteristics just noted.

FIG. 24 DETAILS OF DESIGN OF PROJECTILE

pieces of powder examined was about 21 $\frac{1}{2}$  ft. in length and roughly elliptical in cross-section, the axes being about 1 in. and  $\frac{1}{2}$  in., respectively. It is interesting to note in this case that the powder charge has a weight about 50 per cent greater than that of the projectile. If the weight of the charge were increased, calculations indicate that most of the energy of the gas would be absorbed in the work of accelerating the charge rather than in accelerating the projectile, and no greater muzzle velocity would be obtained.

One of the vital requirements made of the powder is that it burn at a rate sufficiently slow to avoid excessive pressures and

A somewhat recent report by the Bureau of Mines is authority for the statement that the metal-mining industry in this country is now passing through one of the most critical stages in its history, and is confronted by new problems upon the solution and adjustment of which depends, in a large measure, its future welfare and prosperity.

The chief factors, according to the Bureau, contributing to the cost of production are the cost of labor and supplies. It is conceded by our leading mine operators, managers, and engineers that any material reduction in the cost of labor or supplies, within possibly the next two or three years, cannot be anticipated, and it is not thought likely that pre-war prices will ever again prevail. This being true, the mine operator must look in some other direction to effect economies that will lower production costs. If this cannot be accomplished it will mean, in many instances, that mines and metallurgical works will have to be closed and abandoned, which will tend to disorganize the entire industry. How to lower production costs and still maintain the present high standard of wage is the problem that is engaging the serious attention of mine operators and managers over the entire country.

As a solution to this problem it is thought that the most promising field of investigation lies in the direction of systematizing and standardizing mining practice so as to effect economies in the use of both labor and materials. Already some of the large mining companies in the West have conducted extensive experiments and research in this direction, and the results obtained have furnished conclusive proof of the value of standardization of mining practice and mining equipment. For example, the Phelps-Dodge Corporation has made in the past year an exhaustive study of the various underground operations in their mines at Bisbee, Ariz., for the purpose of standardizing the mining practice. The results achieved have been most encouraging, and show that costs can be lowered even in the face of advancing prices in labor and material.

# The Testing of Farm Tractors

By CHARLES H. BENJAMIN<sup>1</sup>, LAFAYETTE, IND.

*The future will unquestionably see a great development of the farm tractor, and the testing of these machines will of necessity be an important factor in that development. To assist in this work there has been installed in the Experiment Station at Purdue University a tractor-testing plant, the features of which are described in the present paper. Briefly, the plant consists of three elements, a treadmill, or moving platform, a traction dynamometer, and an absorption dynamometer, and is capable of testing tractors weighing as high as 12,000 lb. on the driving wheels and giving a drawbar pull of 5000 lb. at a speed of not over 5 m.p.h. A detailed description of the plant follows.*

THE latest machine to claim the attention of the investigator is the farm tractor. Its development has naturally followed that of the automobile and the motor truck, and the farmer, comparatively isolated as he is, finds the use of individual motive power almost a necessity. But, like all newly invented machines, the farm tractor is imperfect, and will not always do the work expected of it. Field tests throw some light on its good

experiment station, is capable of testing tractors weighing as high as 12,000 lb. on the driving wheels and giving a drawbar pull of about 5000 lb. at a speed not to exceed 5 m. per hr.; these tractors being either single- or double-wheel, front or rear drive, or of the caterpillar type, with maximum tread for the double-wheel tractor of 84 in. and a caterpillar length of 96 in., the face of the drivers not being greater than 26 in.

## DESCRIPTION OF THE PLANT

The plant is of the treadmill type having two caterpillar treads of 26 in. width, carried on a structural-steel frame so designed that with little difficulty it can be changed to accommodate the various styles of tractors.

The steelwork consists in part of a main frame made up of three 8-in. I-beams running across the plant resting on permanent supports at each end and on a movable support in the center. All supports being bolted to the foundation.

On the main frame are two rectangular frames which can be

FIG. 1 SIDE ELEVATION OF THE COMPLETE PLANT FOR TESTING TRACTORS

and bad points, but unfortunately they do not always locate the source of poor performance. A laboratory test, on the other hand, if it fairly imitates what we may call standard working conditions, will enable us to compare one machine with another and thus secure information not given by the field test.

To carry on such laboratory tests, apparatus especially designed for the testing of farm tractors has been installed at Purdue University, and it is believed that a description of the installation will be of general interest. The plant itself consists of (1) a treadmill or moving platform, a sort of inverted "caterpillar" supported on driving wheels and idle rollers, and in its turn supporting the driving wheels or lags of the tractor; (2) a traction dynamometer to receive and measure the pull of the tractor; (3) an absorption dynamometer to control and measure the energy transmitted through the treadmill and its supporting wheels.

The plant, which is a permanent equipment for the engineering

moved along the 8-in. I-beams, thus taking care of the different treads of the tractors, or one can be placed in the center to accommodate the single-wheel type. The top of each rectangular frame is made up of four 3-in. I-beams for cross-members, which support the caterpillar tracks. These 3-in. beams can be removed and replaced by a weighing mechanism, so that the weight of the tractor on the driving wheels can be obtained while in operation.

At the rear end of each rectangular frame is a sliding semi-circular track which transfers the caterpillar tread from the top to the bottom track, these tracks being forced endways by means of compression springs which maintain the desired tension on the caterpillar tread.

Under the rectangular frame is a separate track bolted to the foundation for the purpose of carrying the weight of the caterpillar tread on the return. Fig. 1 shows a side elevation of the complete plant.

The caterpillar tread consists of ninety-four 7-in. cast-steel links 26 in. wide, each link being carried on four 5-in. wheels equipped with bronze bearings. These wheels provide support

<sup>1</sup>Dean, Purdue University, Lafayette, Ind. Mem.Am.Soc.M.E. Presented at the Mid-West Sections Meeting, Indianapolis, Ind., October 24 and 25, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

for the links at all times except as they come around 48-in. pulleys at the front end, when the under sides of the links, which are curved to fit, transmit the pull to the 48-in. pulleys. To the upper sides of the links are bolted hard-maple blocks 26 in. long, 6 in. wide and  $4\frac{1}{2}$  in. thick, leaving 1 in. between the blocks. Lugs can be provided on the tractor driver wheels to mesh in the gaps and thus prevent slippage between caterpillar and wheel. Fig. 2 is a general view of the plant.

The 48-in. pulleys which take the pull from the caterpillar tread have glued and riveted to their faces strips of conveyor belting 26 in. wide and  $\frac{1}{2}$  in. thick to reduce slippage between the links and the pulleys. These pulleys are mounted on a 5-in. shaft which is carried on three pedestals equipped with roller bearings. Two of the pedestals can be moved along the shaft to take care of the different positions of the pulleys due to the change of tread

FIG. 2 GENERAL VIEW OF THE PLANT SHOWING THE ELECTRICAL EQUIPMENT

of the tractors. From the end of this shaft the power is transmitted by gears and silent chain to an electric dynamometer located on the main floor of the plant. All bearings in this transmission are either roller or ball type with final connection to the dynamometer by a flexible coupling.

#### THE ELECTRIC DYNAMOMETER

The electric dynamometer which provides the brake load for the plant is of the Sprague Electric Company's standard design, rated at 100 hp. at 1200 r.p.m. and so wired as to operate either as a generator-dynamometer or as a motor-dynamometer. When operating as a generator-dynamometer the energy generated is absorbed by air-cooled rheostats, the resistance of which can be varied to accommodate the load. The rotating part of the dynamometer is supported on ball-bearing pedestals and by suitable linkwork connected to standard scales. These scales are so connected that the only readings necessary to determine the horsepower being transmitted are the weight on the scales and the revolutions per minute of the dynamometer.

#### THE DRAWBAR DYNAMOMETER

The drawbar dynamometer is of the pendulum type, the pendulum and the recording arm being carried by a 5-in. drum hung on ball bearings. The pendulum weight and the recording arm are so proportioned that the record made by the recording pen shows 200 lb. drawbar pull for every inch of movement from the vertical

position. Tangent to the 5-in. drum, a flexible steel plate 0.025 in. thick is fastened connecting it with a reducing arm by a right-and-left-hand coupling nut. The reducing arm is pivoted on ball bearings and is accurately finished on the end to a radius of 36 in. This arm connects with the drawbar of the tractor at a radius of 12 in., thus giving a reduction for the dynamometer weight of three to one. To the 12-in. arm is attached a flat piece of steel 0.045 in. thick which is connected to the  $\frac{3}{4}$ -in. wire rope going to the drawbar of the tractor. This rope passes through a four-wheel guide which can be lowered or raised so that the pull on the tractor will be level at all times and so that there will be no chance for side pull on the dynamometer if the tractor should swing off the center line.

The recording apparatus for the drawbar dynamometer consists of a vertical brass table which can be moved along suitable guides to take care of the different loads.

The 10-in. record paper is carried over the table from the lower roll to the upper, the winding mechanism being driven from the main 5-in. shaft of the plant so that the speed of the paper is in exact proportion to the speed of the tractor. Above the recording table are two recording arms which can be moved along a graduated scale, one arm with its pen marking the zero line for the test; i. e., if test is run at 2000 lb. drawbar pull, the zero line would be placed at 1500 or 1800 lb., thus giving a card which would be easy to measure. The second recording arm would be set at the desired load to be carried. This arm will have fastened to it a fine wire with a weight at the lower end which will keep the line plumb and straight at all times. As the operator looks at the recorder, he will see a line which will represent the load he is carrying on the tractor and by this he will be able to keep the electric-dynamometer adjustment correct. Along the side of the table is a sliding electric time recorder which can be set opposite the recording pen so that the time record will correspond to the load record.

A weighing mechanism will be placed under the guiding axle of the tractor so that the changing load on the guide wheel can be measured while the tractor

is under load, thus giving a check on the force transmitted to the drawbar.

#### TYPES OF EXPERIMENTS MADE

The experiments which can be made on a machine such as has been described are of a twofold character:

1 Those made with the tractor to be tested mounted on the moving platform and run in its usual manner, transmitting its energy through the platform, the wheels and the geared train to the generator which acts as a brake.

2 Those in which the engine and main driving shaft of the tractor are connected more or less directly with the generator either with or without the use of the transmission gears, the tractor wheels and the moving platform being "cut out."

The first may perhaps be termed the commercial and the second the scientific test. In the first we have field conditions and field operation imitated. The tractor is run at different speeds and under different loads and the economy or efficiency is determined in the gross, in terms of the drawbar pull and the gasoline consumption.

This would be followed by field or road tests to determine other practical characteristics of the tractor as they are affected by out-of-door conditions. The efficiency of the tractor considered merely

(Continued on page 132)

# Research and Social Evolution

By C. F. HIRSHFELD<sup>1</sup>, DETROIT, MICH.

*Research, according to the author of the following paper, is the search for facts, and industrial research is the search for industrial facts. This, he points out, opens a broad and almost unlimited field for the research worker. The value of research lies in substituting methods of assurance based on fact for those of guess which, in the past, have been the bases of judgments made by industrial leaders. Nor is the author pleading alone for what he terms material research but for economic research as well, and most particularly for sociological research, believing that our basic knowledge and control of human relations have not kept abreast of social evolution.*

THE study of history reveals a great similarity in the social and economic conditions following wars of great magnitude. There is always a period of topsyturvydom during which radicals of all kinds command large audiences and when individuals and nations act as though they had been relieved suddenly of all historical restrictions and bonds and were free to proceed unhampered in the pursuit of any sort of evolutionary or revolutionary scheme which met their individual or collective fancies.

This period always flows gradually into one in which the necessity of continuing an ordered social life is appreciated by the great majority, and the world, or that part of it affected by the war, settles down once more to the production of wealth and the pursuit of happiness upon a plane and according to methods not greatly different from those in use before the cataclysm.

The real lessons of the war and the lasting results thereof are seldom appreciated until they can be viewed in retrospect, and often through a vista of many years.

The present situation bids fair to duplicate the past. We are apparently just emerging from topsyturvydom and moving toward a more or less ordered existence. We are beginning to appreciate the fact that sociological surgery, like human surgery, has as yet certain limitations. We may perform operations of some sorts without seriously endangering a fairly normal patient, but when the severity of the operation exceeds a certain limit the patient is apt to succumb to shock, even after a most successful operation from the surgeon's viewpoint.

I feel that it is well to bear such facts in mind when discussing research and its application to industry in this country. The public at large seems to believe that industrial research did not exist in these United States before the war; that the phenomenal performance of Germany and her allies was due to the development of such research in Germany; and that we are now about to take up work of this sort in characteristic American fashion, producing over night a dozen or more research laboratories for every one originally possessed by Germany. The facts are that industrial research was fairly common in this country before the war; that Germany's performance, in so far as it depended upon research, was largely based on the utilization of the results of research rather than upon the uncovering of new facts; and that to multiply research laboratories and facilities in this country at too rapid a rate would lead to chaos, waste and business failure instead of acting as a healthy stimulant to a slightly neurotic patient.

We must not expect the war to revolutionize over night our methods of producing and of doing business any more than we can expect it suddenly to "emancipate" labor. The fact that we are now trying to enunciate and codify principles governing the relations between employer and employee which have been in the process of development for decades should not lead us to attribute the principles themselves to the war. The disturbed conditions incident to the war merely serve to focus attention upon the problem. This is a convenient time for taking account of stock before we start out once more in ordered fashion to develop still further.

Similarly, there has been growing in industry during the two decades just past an appreciation of the fact that refined methods of analysis produce results, and the war has simply served to focus attention upon the haphazard way in which industry has adopted and utilized such methods. This is unquestionably the time at which we can best study what we have achieved in the application of industrial research, and at which we can best plan the future development insofar as it is controllable. If you will look over the papers which have been presented before this organization and others of similar type during the past three years, you will discover that some of the best minds in the country are already engaged in just such a task.

## POPULAR IMPRESSIONS OF RESEARCH \*

There is another popular impression which I believe to be basically incorrect. Research is regarded as a name for the efforts of individuals who spend their working hours in physical and chemical laboratories delving into the so-called secrets of nature for the purpose of extracting hitherto hidden facts or formulae which may be expected to have commercial value. To me this is entirely too narrow an interpretation. I regard *research* as the search for facts, and I regard *industrial research* as the quest for facts which have immediate industrial value. Research as now pictured by the multitude may be called *material research*. Industrial research must include many other varieties if it is to achieve its end, particularly economic research and sociologic research. Questions of economic and sociologic types are just as amenable to laboratory treatment as are problems in the proper method of heat-treating a given grade of steel or in the modifications required to take account of mass action in conducting chemical reactions on a commercial scale.

If research be regarded merely as the determination of facts, every department of industry is a proper field for research and possibly can be benefited thereby. In fact, if this definition be adopted, modern research is merely an organized or ordered development of the methods which have been in use for generations. Every executive and every individual in charge of industrial activities has had to make decisions, and, in general, has determined facts on which to base these decisions insofar as that has been possible. Unfortunately the determination of facts in many different lines by one individual and at the rate required to keep pace with the evolution of the industrial world is often impossible, and as a consequence most of our successful executives have fulfilled Elbert Hubbard's definition—they decided quickly and were sometimes right. The marvel is that they were right in such a large proportion of their decisions.

All that we can hope to do by research is to make available for such men the facts upon which to base a greater proportion of their decisions. They will thus have to depend upon judgment, instinct, intuition, or guess, as you like, for a smaller proportion of their decisions, and their work will be just that much nearer to an absolute basis.

## THE FUTURE OF RESEARCH

I do not like to pose as a prophet—I prefer to have some honor in my own country if it is obtainable. However, I believe it is patent that our industrial development on its material side is already outstripping the economic and sociologic development required to stabilize it. We are learning to produce in greater quantities and in greater varieties daily, and our attention is so focused on this work that we are giving insufficient thought to the problems of finance, distribution and utilization and to the desires, ambitions and hopes which we are creating.

The literature of the day is so full of articles giving the results of investigations in the field of heat treatment that no manufac-

<sup>1</sup> Chief, Research Dept., The Detroit Edison Co., Jun. Am. Soc. M. E. Presented at the Mid-West Sections Meeting, Indianapolis, Ind., October 24 and 25, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

turer of steel products can plead ignorance of the fact that exact information is available if he chooses to make use of it. On the other hand, where is that same manufacturer to learn the facts with respect to the advisability of making plant extensions during periods of rising as against falling prices, or during periods of decreasing business failures as against periods of increasing failures? Or where is he to determine facts with respect to the reasons why bonus systems or profit-sharing systems succeed in some places and fail in others? Or where is he to obtain information with respect to the relationship existing between the rate of increase of wages in his plant or in his industry and the rate of increase of living costs? Research in such fields is conducted to a limited extent and certain publications are issued for the purpose of distributing the results, but comparatively few industries seem to have recognized the necessity of applying this sort of research to the problems of industry.

Does it not appear that in the sudden public appreciation of the advantages to be gained from material research we are threatened with a one-sided development which can only lead to trouble unless corrected at the start? Does it not appear desirable for organizations such as this Society to bring to the attention of the public the fact that no decision of any sort need rest on guesswork if facilities for all the necessary types of research are available?

I am not now concerned with the way in which research is to be conducted or financed. For my present purposes it is immaterial whether the federal government pays for this, the state government pays for that, and the individual producers or a group of producers pay for something else.

I am concerned with developing appreciation of the fact that what we now call research is merely an extension and refinement

of methods previously in use; with driving home the fact that material research is only one of the numerous varieties required to continue the present industrial development; and with spreading the doctrine that it is good business to obtain such information as is necessary to enable our industrial executives to base their decisions more largely upon determined facts and to a lesser extent upon so-called judgment. I feel particularly that the continued stable development of the industrial age depends almost entirely upon our ability to bring to our executives those facts which will enable them to stabilize the social structure within which industrialism is contained and has its growth. I see no way of doing this other than by painstaking research along economic and sociologic lines at such a rate as to keep pace with the results attained by the application of material research which industry itself may be depended upon to develop at an ever-increasing rate.

I admit that my program is large, but the problem with which we are faced is large. We of this country, in common with the rest of the civilized world, have developed to a point where the conditions we have created are leading us to question the adequacy and even the validity of what we have regarded as fundamental concepts in the relation of man to man and of nation to nation. Some of us attribute this condition to the rapid development of industry, others to the growth of social and class consciousness, and still others to the continued upward progress of man. Attribute it to what you will, it is a fact that parallel to our development of factories, modern methods of production and of ways and means of bending natural forces and laws to our ends, there has occurred a development in human relations about which we have much less basic knowledge and over which we can exercise correspondingly less control. Is not a rather large program justified by such a set of conditions?

## Research and Industrial Wastes

By GEORGE S. HESSENBRUCH,<sup>1</sup> ST. LOUIS, MO.

*In the paper which follows the author introduces his subject by calling attention to the lack of interest in research which existed previous to the war. He divides research into two classes which he calls "pure scientific research" and "industrial research," and points out that the latter class has a direct financial return to the industry concerned. He makes a strong plea for research on the subject of industrial wastes and closes his paper by describing a research laboratory now contemplated for pursuing this type of investigation.*

UNTIL a few years ago, research in the United States was not looked upon with great favor, except by those few who realized and knew what it had accomplished and what it meant to science. The general opinion among the laity was that only a crank could be interested in research that no special benefit would be derived from it in a commercial way. Its unbounded limits were not recognized by the general manufacturer. No doubt many men in the industries often wished they knew why such and such was the case and what would happen if such and such was done and what might be developed. Research, however, was looked more upon as a kind of inventive genius with which only a few were gifted and not as a science.

Up to that time there were few laboratories devoted to this work and these few were not sufficiently equipped to accomplish very much. Furthermore, their endeavor was mostly along some specific and special line of investigation for a particular industry. But now largely as a result of the world war and the impulse created by it for development along all scientific lines and the consequent industrial activity, manufacturers have come to the realization that activity in research is one of the essentials in the progress of industry, that it has, in many instances proved highly profitable, opened up tremendous fields for industrial endeavor and given them a vast amount of accurate and definite information and data

on subjects that previously had only been guess work and chance.

The subject of research can be divided into two distinct classes, namely, "pure scientific research" and what might be called "industrial research." Pure scientific research in most cases does not show very great immediate financial gains and therefore must be undertaken for the pure love of science and knowledge. It requires an investigator of a highly trained mind and peculiar character for the devotion to its cause. He must be of a very analytical trend of mind, possess considerable knowledge, and have unlimited patience and courage. He must be unselfish and have the ability of great concentration. Pure scientific research does not, however, show very great financial gain. The unmeasurable value and importance of this branch is not realized, for with but a few exceptions has a life-long work in this branch brought a commensurate financial return to the one devoting himself to it. Nevertheless, this branch is of the greatest importance and any accomplishment or new discovery in it is of inestimable value. If it were not for pure scientific research we would have no foundation for science. Its discoveries bring forth and determine the fundamentals and principles upon which further development is based and make them available for industrial enterprise and exploitation. At this point the engineer and chemist steps in and applies these new fundamentals and principles, develops them and gradually produces for the world a new piece of apparatus, machinery or process such as in some instances have revolutionized an entire industry. The need of pure scientific research therefore is absolutely essential.

### INDUSTRIAL RESEARCH

Industrial research, although highly scientific in principle, might be classed as the branch with the greatest chance of financial returns and for this reason it attracts more attention, as it is more remunerative both to the worker and investigator as well as the investor and industry. It develops known facts still further, and

<sup>1</sup> President, Industrial Engineers Corporation. Mem. Am. Soc. M. E.

<sup>2</sup> Presented at the Mid-West Sections Meeting, Indianapolis, Ind., October 24 and 25, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

investigates established principles, fundamentals and materials with the sole object in view of making these principles, fundamentals or materials of greater commercial value and more remunerative and available for industrial purposes. The world war and its consequent activities have given this branch of research a great impetus during the last few years in the United States. A great number of the larger corporations are establishing or have established research laboratories. These laboratories are, however, mostly equipped for investigations along the special line of endeavor of the particular corporation. A few private laboratories have been established for the purpose of investigating any subject that may be presented to them by a manufacturer who does not have a laboratory of his own, or who cannot justify the expense of maintaining one, but who can afford to obtain more definite and accurate knowledge on the materials or methods of manufacture pertinent to his particular endeavor. These laboratories undertake this work for a fee and results of value are sometimes obtained; at other times, however, the investigation, although conscientiously carried forward, is bare of results except as to data.

The United States Government has realized the meaning of industrial research and is giving it its support, and many societies and organizations are collecting data as to laboratories, etc., and in this way industrial as well as pure scientific research is gradually receiving more and more attention.

#### INVESTIGATION OF WASTES

In industrial research would be included the investigations of wastes. This subject, in the writer's opinion, is one of considerable importance, for in many instances the financial return from the wastes, when properly processed and obtained from the raw materials in a manufacturing plant, have been greater than the return from the actual manufactured article made in this same plant.

Today we are confronted from all over the United States by the cry of increased production. Every manufacturer is striving his utmost to help this movement. In fact, it is the solution or at least an amelioration of many of the evils that threaten us seriously. It is but natural for us to turn toward the utilization of wastes and waste materials, which is the most economical and beneficial way to help this movement. Reducing these enormous wastes or utilizing them in some way or other by suitable processing will not only save our national resources from being depleted more rapidly, but it will also teach the manufacturer to be circumspect. It will reduce costs, establish new industrial undertakings, give employment to more people, open up new channels of commerce, induce capital to invest in new enterprises, increase the production of our soil and finally bring about the one most important status, namely, independence.

One benefit, if we may call it that, arising out of the world war has been that the American manufacturer is today more willing to be convinced in regard to the loss he is incurring daily by the non-utilization of waste materials. A few years ago the writer had the sad experience of being laughed at when putting before several manufacturers a plan by which their waste material would net them a greater return than the article they were producing in their factories. It was only a question of the proper processing of the wastes to make a salable and valuable product, a product that had a big demand and which was being imported. The processing was demonstrated to them, but they frankly said they did not wish to go into the chemical business—they were manufacturers of a certain article and did not care to undertake a new line and would not be interested.

The writer does not wish to minimize the efforts that have been put forth or disparage the good work that has been accomplished by such institutions as the Mellon Institute in Pittsburgh, our own Government laboratories in Washington and Pittsburgh, the Rensselaer Polytechnic Institute and the many private laboratories throughout the country. They have all done good work and are accomplishing a great deal for the benefit of industry and the public in general, but he would like to see a concerted move in the direction of research of wastes and their utilization. In his opinion such research would be of great value, and a brief de-

scription of a laboratory for conducting such investigations will doubtless be of interest. Its scheme of operation is so novel and unique as regards the financial returns of the undertaking that the writer feels that every manufacturer, no matter how large or small will be glad to avail himself of the chance to have his waste materials investigated, and developed if possible. It is contemplated that the laboratory will be one of the best-equipped laboratories in the United States, and that the highest possible class of research workers only will be employed. No fees are to be charged and no investigations will be undertaken for a fee, nor will there be any testing of materials. The laboratory is to be devoted purely to wastes and the utilization of wastes. The data collected will be available to any accredited scientist, research worker, or institute free of charge and cannot under any circumstances be utilized commercially except by special sanction of the laboratory management. All processes will be properly patented and the patents will be the property of the laboratory for such disposition as the board of management may deem best advisable. The manufacturer who has sent in the waste will, after proper investigation, be advised in the form of a report of the possibilities. The report will show the investment required for the proposed undertaking, the estimated operating cost, the revenue, the present and future markets and all data such as are required for the sound and proper understanding of the proposed undertaking. If requested, plans and specifications will be furnished for the entire establishment and operation properly started and temporarily superintended. This latter part of course will call for the regular engineering fee as established in the engineering profession. The manufacturer will be assisted in any way it is possible for the laboratory to serve him. In short, every effort will be made to give the manufacturer the full benefit that expert knowledge and investigation in all of the engineering lines can give, the ultimate result in view being to see the establishment of an undertaking that will in some manner or form utilize this waste and bring about conservation.

It is fully realized that a large amount of capital will be required and that the laboratory in all probability will not become self-sustaining for a period of three or four years, but under the scheme as laid out by the originators of the project it is figured that after that time it will become remunerative financially as well as bring about a great benefit to the industries and the public in general. An additional benefit of inestimable value will be the large amount of accurate knowledge and data that will be obtained and placed at the disposal of all mankind, and it stands to reason that land in hand with industrial research will go purely scientific research, the results of which will be available to all and will be given out for the benefit of science in general.

Following apparently satisfactory test-block studies of a synthetic airplane-engine fuel known commercially as Alcegas and composed of 38 parts alcohol, 19 parts benzol, 4 parts toluol, 30 parts gasoline and 7½ parts ether, the Post Office Department arranged for a test of the fuel under service conditions in the Air Mail.

Mail plane No. 35, a Curtiss Model R4 machine equipped with a high-compression Liberty 12 motor, was assigned for the work. The check plane, flying the opposite trips during the same period with high-test aviation gasoline, being mail plane No. 34, also a Curtiss Model R4 plane, equipped with a low-compression Liberty 12 motor.

Thirty-one trips were flown between New York and Washington, being 218-mile non-stop flights, on the regular air-mail schedule between August 4 and September 19, 1919. The flights made by the gasoline ship numbered nineteen.

The tests indicate a saving of 3.3 gal. of fuel per hr. in favor of the alcohol fuel. Noting the revolutions per minute, however, the saving is even greater, as alcohol fuel shows 1514.3 r.p.m. as against 1507.8 r.p.m. with gasoline. This means that not only is there a saving of 3.3 gal. of fuel per hr., but that 6.5 r.p.m. are gained also by the use of the alcohol fuel.

Alcohol fuel also shows a saving in lubricating oil. The average for this fuel was 4.4 qt. per hr. as against 4.98 qt. per hr. for gasoline, or a net saving of 0.58 qt. per hr. This saving is thought to be due to the greater thermal efficiency displayed by alcohol.

## FLANGES FOR CAST-IRON PIPE

A PAPER by Mr. John Knickerbacker, read before the American Water Works Association last June, invites closer co-operation from the Cast Iron Pipe Makers and the A.S.M.E. Committee on Standardization of Flanges and Pipe Fittings. Mr. Knickerbacker recalls the need for adoption of standard flanges for light cast-iron pipe, and presents diagrams visualizing the

different standards and semi-standards now existing for each size.

It will be remembered that an A.S.M.E. Committee has had this subject, flange ends for all weights of pipe, under constant consideration since 1892, and it is to the 1918 Report of this Committee that Mr. Knickerbacker especially refers. Therefore the memorandum below by Arthur R. Baylis, Chairman of the A.S.M.E. Committee, is interesting, as explaining the difficulties under which the Committee was obliged to work.

CONVENTIONS USED IN DIAGRAMS

--- INDICATES 125° AM STD.

— PROPOSED 50° AM STD. OF MARCH 24-1916

••••• ADDITIONS & ALTERATIONS MADE IN PROPOSED 50° AM STD. OF MAY 18-1918

When the A.S.M.E. Committee on Standardization of Flanges and Pipe Fittings first commenced work on the new low-pressure standard, consideration was given to an entirely new set of dimensions propor-

TABLE 1 PROPOSED LOW-PRESSURE STANDARD FOR END FLANGES, BOLTINGS AND BODY THICKNESS—30 LB. WORKING PRESSURE

Size	Diameter of Flange	Flange Thickness	Bolt Circle Diameter	Number of Bolts	Size of Bolts	Body Thickness	Size	Diameter of Flange	Flange Thickness	Bolt Circle Diameter	Number of Bolts	Size of Bolts	Body Thickness

tioned to the specified working pressure and pipe diameters. Other considerations developed which influenced the Committee in arriving at the dimensions set forth in the present 50-lb. American standard.

The Committee of Manufacturers on Standardization of Fittings and Valves held an annual meeting on April 19, 1916, at which it discussed a proposed low-pressure standard. It finally authorized a subcommittee to conclude the matter in collaboration with the A.S.M.E. Committee. Their report, which maintains as far as possible interchangeability with the present 125-lb. American standard for flange- and bolt-circle diameters and number and diameter of bolts, is set forth in Table 1.

In determining flange thickness, pipe sizes were separated into groups, a common thickness of flanges being selected for each group, reducing to a minimum the number of stock bolts required, the diameters of bolts being standardized as well.

It does not appear that Mr. Knickerhacker's reference to foundry difficulties on the standardized flanges is well taken, as the permissible variation between thickness of flange and pipe body metal largely depends on the size and shape of the connecting fillet. Good safe castings can be made if the thin metal is gradually tapered into the thick.

In grouping the pipe sizes as mentioned above, it naturally follows that the smallest pipe in each group has a heavy flange while the largest pipe has a light one. When standards are formulated on the basis of interchangeability, with the object of reducing the number of patterns, templates and confusion in construction work, general proportion is of necessity somewhat sacrificed, and it is difficult to determine just where to draw the line. Sizes were selected for minimum thickness of pipe body metal closely following those of the American Water Works Association, class "B" pipe. The new standard is considered ample to meet all physical requirements.

The curves shown here are self-explanatory and a study of them largely explains the standards adopted. These curves were used during Committee discussions in preparing the new low-pressure standard.

Our Committee will be glad to cooperate further with any engineering organization interested in this subject.

(Signed) ARTHUR R. BAYLIS, Chairman

A.S.M.E. Committee on Standardization of Flanges and Pipe Fittings.

# ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

## A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulae or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

**Apparatus and Instruments A1-20.** Electrical Measuring Instruments. An exhaustive paper on the accuracy of commercial electrical measurements requested by the Committee on Instruments and Measurements of the A. I. E. E. has been furnished and submitted to the Chairman of the Committee. It is scheduled for the Convention in February. It discusses the accuracy required, choice, installation, use, and maintenance of instruments, conditions of use, features of design, sources of error and improvement. Address Bureau of Standards, S. W. Stratton, Director, Washington, D. C.

**Fuels, Gas, Tar and Coke A1-20.** Sulphur in Coals. A study of the forms in which sulphur occurs in coals. Bulletin No. 111 of the Engineering Experiment Station of the University of Illinois by A. R. Powell with S. W. Parr. The Bulletin gives the present status of the knowledge of sulphur in coal, the methods used in analyzing the changes in the form of sulphur in the coal, and also conclusions which have been abstracted.

1 The sulphur of coal occurs in four characteristic forms:

- (a) The resinic organic type.
- (b) The humus organic type.
- (c) The pyritic or marcasitic inorganic form, and
- (d) The sulphate sulphur.

2 Early methods of determining the forms of sulphur gave high results for pyritic sulphur and low results for organic. The methods developed in the Bulletin are more nearly accurate.

3 Some of the sulphur in coal is oxidized to the form of sulphate. Length of time and standing accomplished this.

4 The action mentioned in 3 is hastened by the presence of bacteria or some catalytic agent.

5 The amount of soluble sulphate formed is less than it would be if the amount of soluble iron were taken as a criterion. Some of the oxidized sulphur combined with the organic matter of the coal.

6 When coal is coked the sulphate sulphur is retained by the coke, the pyritic sulphur is partially volatilized, most of the resinic sulphur is left in the coke and the humus sulphur is partially volatilized.

7 The forms of sulphur in the coke were studied but not fully identified.

8 During the coking process secondary reactions between the constituents of the coal and the decomposed sulphur compounds affect the quantity of sulphur retained by the coke.

Address Director of Engineering, Experiment Station, University of Illinois, Urbana, Ill.

**Heat A1-20.** Hot-Air Pipes with Thin Asbestos. In making simple tests on relative thermo-resistance of layers of asbestos paper when applied loosely and tightly, it was observed that tin vessels containing hot water would cool less rapidly than the same vessels when wrapped tightly with one layer of sheet asbestos 0.013 in. thick. It was found that it was necessary to have asbestos at least 1/16-in. in thickness to be equal in heat conductivity to the bare pipe. Address T. S. Taylor, Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa.

**Metallurgy and Metallography A1-20.** Lead and Embrittlement. It has been found that the rate at which intercrystalline brittleness is brought about is proportional to the amount of impurities and to the concentration of acid in the solution in which the lead is placed. Practically all impurities which are found are lodged between the grains. The preferential attack by the corroding agents for these impurities and perhaps for the amorphous intercrystalline cement accounts for the brittleness. Investigations showed that specimens of exceptionally pure lead (99.99 per cent) when immersed in a neutral solution of an acetate for twenty-four days became appreciably embrittled by the formation of minute intercrystalline fissures. No evidence of the existence of allotropic form of lead similar to gray tin could be obtained. Address Bureau of Standards, S. W. Stratton, Director, Washington, D. C.

**Properties of Engineering Materials A1-20.** Rope. The Action of Acid on Rope with Protective Coatings. Tests of manila rope to determine the effect of asphaltum compound used as a protection to rope against action of muriatic acid show that rope so treated deteriorates as completely as untreated rope. Address Bureau of Standards, S. W. Stratton, Director, Washington, D. C.

## B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work, and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

**Aircraft B1-20.** Propellers. Investigation of airplane propellers in connection with National Advisory Committee for Aeronautics. Prof. W. F. Durand and E. P. Leslie, Stanford University, Cal.

**Apparatus and Instruments B1-20.** Recording Thermometers. A study of the permanence and accuracy of initial adjustment and sensitivity, of recording thermometers having an upper limit of reading of about 320 deg. Fahr., together with a comparative examination of the mechanical excellence and convenience of manipulation and observation of the various types. The tests planned are such as to develop the factors of hysteresis, including pen friction, time lag, fatigue, constancy of zero adjustment and of the elastic properties of the Bourdon tube under frequently repeated temperature cycles. Work of the Sub-Committee on the Permanency and Accuracy of Engineering Instruments, F. J. Schlink, Chairman, Address P. J. Schlink, Physicist, Firestone Tire and Rubber Company, Akron, Ohio.

**Apparatus and Instruments B2-20.** Oxy-acetylene. An investigation of the apparatus for oxy-acetylene welding and cutting. Method of determining the specific-heat ratio of acetylene passing through acetylene meter has been completed. Bureau of Standards. Address S. W. Stratton, Director, Washington, D. C.

**Automotive Vehicles and Equipment B1-20.** Radiators. Heat tests of auto radiators. Sheffield Scientific School, Yale University. Address Prof. L. P. Breckenridge, New Haven, Conn.

**Friction B1-20.** Ball and Roller Bearings. The friction of ball and roller bearings. Sheffield Scientific School, Yale University. Address Prof. L. P. Breckenridge, New Haven, Conn.

**Heat B1-20.** Heat Transmission in Boiler Tubes. Sheffield Scientific School, Yale University. Address Prof. L. P. Breckenridge, New Haven, Conn.

**Heat B2-20.** Hot-Blast Heater Experiments. Sheffield Scientific School, Yale University. Address Prof. L. P. Breckenridge, New Haven, Conn.

**Heat B1-20.** Heat Transfer. Research relating to the development of satisfactory commercial apparatus for the transfer of heat between fluids, vapors and gases and to include a study of the transfer of heat between metal surfaces and fluids of widely varying viscosities. Prof. W. R. Eckert, Stanford University, Cal.

**Internal-Combustion Motors B1-20.** Modified Diesel Engine. Development of special or modified form of Diesel engine to use kerosene and distillate. Prof. C. N. Cross, Stanford University, Cal.

**Machine Design B1-20.** Ball Bearings. Development of proper type and mounting of ball bearings for deep-well pumps and centrifugal pumps. S. C. Kyle, Italtio Building, San Francisco, Cal.

**Machine Design B2-20.** Gear Teeth. Investigations of the wear of gear teeth under loaded conditions, including the influence of a varying intensity of load, materials, tooth forms, and lubrication. Prof. G. H. Marx, Stanford University, Cal.

**Machine Design B3-20.** Locomotive Packing-Ring Investigations. It has been found that low-sulphur air-furnace iron is more suitable for locomotive packing rings, bushings, valves and piston rings than cupola iron. It appears desirable that the present maximum allowable sulphur limit be lowered and that the minimum transverse strength of castings be slightly increased. It has not been possible to establish a relation between laboratory and service tests. A report on this investigation is now practically complete. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Metallurgy and Metallography B1-20.** Steel. Development of steel of suitable grade for pins of buckets on gold-dredging machinery. Pins have diameters from 3 to 7½ in. G. L. Hurst, Union Plant, Bethlehem Shipbuilding Corporation, San Francisco, Cal.

**Metallurgy and Metallography B2-20.** Electric Furnaces. Improvements in electric furnaces with special reference to the following applications:

- a The melting of steel scrap for steel castings.
- b The melting of steel scrap and ferroalloys into tool steels.
- c The heat treatment of steel castings for annealing or tempering.
- d The melting of non-ferrous metals for commercial castings in marine work.

Address C. M. Gunn, 444 Market St., San Francisco, Cal.

**Properties of Engineering Materials B1-20.** Expansion of Marble. Two slabs of Tennessee marble and one slab of Vermont marble have been exposed to the weather at the Bureau of Standards. During the first three months a considerable change in dimensions was shown, after which the dimensions remained fairly constant. One of the Tennessee slabs expanded 0.02 per cent and the other 0.13 per cent of its length, while Vermont marble contracted 0.04 per cent of its length. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Properties of Engineering Materials B3-20.** Tests of Materials before acceptance and to determine cause of failure and strength of electric welds. (Tests 1117-1119-1140-1171-1192-1203-1205-1223 and 1069.) Naval Experiment Station, Annapolis, Md. Address Bureau of Steam Engineering, Washington, D. C.

**Properties of Engineering Materials B3-20.** Bearing Metals. Tests of bearing metals. (Tests 1101-1114-1145-1092-869.) U. S. Naval Experiment Station, Annapolis, Md. Address Bureau of Steam Engineering, Washington, D. C.

**Properties of Engineering Materials B4-20.** Repeated Stress and Impact. Investigation of endurance and impact resistance of metals. Test 1220. U. S. Naval Experiment Station, Annapolis, Md. Address Bureau of Steam Engineering, Washington, D. C.

**Properties of Engineering Materials B5-20.** Magnetic Analysis. The Bureau of Standards is engaged at present on a study of the correlation between magnetic properties of steel and its structure and mechanical properties, and the development, methods and apparatus for the application of magnetic analysis in a practical way. A method has already been developed to determine the degree of homogeneity along the length of a relatively long piece. The quality of heat treatment is also being investigated by magnetic methods. Address Bureau of Standards, S. W. Stratton, Director, Washington, D. C.

**Pumps B1-20.** Air Chambers. Determination of proper size of air chambers upon reciprocating pumps. No. 1231. U. S. Naval Experiment Station, Annapolis, Md. Address Bureau of Steam Engineering, Washington, D. C.

**Railroad Tracks and Signals B1-20.** Rail Investigations. The Bureau of Standards is at present making a critical study of available literature for the purpose of classifying rail failures and test data preparatory to initiating an extensive series to discover cause and remedy for such accidents. Bureau of Standards, Address S. W. Stratton, Director, Washington, D. C.

**Steam Power B1-20.** Steam Power Plants for Automobiles. The Doble laboratories of San Francisco are investigating the development of steam power plants for automobiles under several divisions:

- a Systems of combustion using kerosene and cheaper grades of fuel without the formation of soot and carbon deposits.
- b The construction of the combustion system to make it automatic and subject to control by the boiler conditions.
- c A fuel and fire automatic control.
- d The development of a high-pressure boiler of maximum thermal efficiency.
- e The development of a new type of steam engine with high economy, flexibility of control and utilization of high-pressure steam with high superheat. Address Doble Laboratories, San Francisco, Cal.

**Transmission B1-20.** Hydraulic Dynamometers as Transmission Devices. H. B. Langille, University of California, Berkeley, Cal.

#### C—RESEARCH PROBLEMS

The purpose of this section of Engineering Research is to bring together persons who desire cooperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that

those desiring cooperation or aid will state problems for publication in this section.

**Boilers and Accessories C1-20.** High-Capacity Boiler. Design, construction and testing of boilers for high capacities. Address Sheffield Scientific School, Yale University, Prof. L. P. Breckenridge, New Haven, Conn.

**Fuels, Gas, Tar and Coke C1-20.** Pig-Iron Coke for Making Pig Iron on the Pacific Coast. Address Robert M. Hale, 220 Battery St., San Francisco, Cal.

**Heat C1-20.** Radiation. Heat radiation from gases to solids at high temperatures. Sheffield Scientific School, Yale University. Address Prof. L. P. Breckenridge, New Haven, Conn.

**Heating C1-20.** New Method of Heating by Reversal of Thermodynamic Cycle. Reverse a cycle to discharge high-temperature heat and also use discharge from engine driving cycle. Address J. G. De Remer, Kialto Building, San Francisco, Cal.

**Hydraulics C1-20.** Measurements. The measurement of the flow of fluids. Sheffield Scientific School. Address Prof. L. P. Breckenridge, New Haven, Conn.

**Metallurgy and Metallography C1-20.** Spelter. A continuous process for producing spelter. See letter from Prof. W. F. Durand in the Research Section of the January number of MECHANICAL ENGINEERING. Address Robert M. Hale, 220 Battery St., San Francisco, Cal.

#### D—RESEARCH EQUIPMENT

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

**Sheffield Scientific School, Yale University D1-20.** Research Laboratory. The Research Laboratory of the Mechanical Engineering Department of Sheffield Scientific School is equipped as follows:

- Heating boilers for using anthracite and bituminous coal
- Exhaust fan and heater stacks
- Automobile-radiator testing laboratory
- Automobile testing drum
- Sprague electric dynamometer
- Material-testing machines up to 150,000 lb.
- Gas-explosion apparatus
- 150-hp. water-tube boiler
- 50-hp. two-stage air compressor
- Gas producer
- Gas and gasoline engines
- Steam engines and condensers
- Airplane engines of the following makes:
  - Two 400-hp. Liberty motors
  - Two 100-hp. Hall-Scott motors
  - Two 200-hp. Curtiss V-2 motors
  - Two 150-hp. Hispano-Suiza motors
  - Two 100-hp. Curtiss OXX motors, and
  - Two 100-hp. Gnome motors.

Sheffield Scientific School, Yale University. Address Prof. L. P. Breckenridge, New Haven, Conn.

#### E—RESEARCH PERSONNEL

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

**Connecticut Research Laboratories E1-20.** Through the Research Committee of the Local Sections in Connecticut the names of the following laboratories in the neighborhood of New Haven have been collected. Other lists are to follow:

- The Acme Wire Company. Address Dr. R. W. Langley, New Haven, Conn.
- American Brass Company. Address J. A. Coe, Waterbury, Conn.
- English and Mersick Co. Address S. M. Bradley, New Haven, Conn.
- Farrell Foundry and Machine Co. Address Walter Perry, 2nd Vice-President, Ansonia, Conn.
- Groton Iron Works. Address H. O. Trowbridge, Groton, Conn.
- Greist Mfg. Co. Address H. M. Greist, New Haven, Conn.
- Malleable Iron Fittings Co. Address A. E. Hammer, New Haven, Conn.
- New Haven Gaslight Co. Address J. A. Norcross, New Haven, Conn.

Seoville Mfg. Co. R. S. Sperry, Waterbury, Conn.  
Sargent & Co. Address Henry B. Sargent, New Haven, Conn.  
Winchester Repeating Arms Co. Address Edwin Pugsley, New Haven, Conn.

*Sheffield Scientific School, Yale University EI-20.* The research work of the Sheffield Scientific School is given by the following titles of articles published:

#### F—BIBLIOGRAPHIES

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared.

## THE NEW MECHANICAL ENGINEERING LABORATORY, COLLEGE OF ENGINEERING, UNIVERSITY OF ILLINOIS

By CHARLES RUSS RICHARDS,<sup>1</sup> URBANA, ILL.

THE following description of the Power Laboratory of the Department of Mechanical Engineering of the University of Illinois presents the facilities for instruction and research which are afforded by but one of the many laboratories of the College of Engineering, and which are available for the research work of the Engineering Experiment Station. Each department of the College of Engineering is represented in the Engineering Experiment Station and is conducting investigations with funds appropriated for the purpose by the University, or with funds for special coöperative investigations provided by outside interests. The Station is prepared to undertake research work in architecture and architectural engineering, ceramic engineering, industrial chemistry, civil engineering, electrical engineering, theoretical and applied mechanics, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, and railway engineering. The results of completed investigations are published as bulletins of the Engineering Experiment Station, which are distributed free upon request. At present 114 bulletins and 8 circulars have been published.

The following is a partial list of investigations which are being conducted with funds provided by the University: Investigations of the viscosity of glass; of certain ceramic materials and processes; of the drainage of land; of monolithic construction of highways; of riveted steel structures; of the electrical properties of steel alloys; of acid-resisting alloys; of various properties of coal; of the manufacture of gas; of reinforced concrete and other materials of construction; of the explosion of gaseous mixtures; of the gas-engine cycle; of twist drills and the drilling of metals; of coal mining; of the subsidence of land from mining; of heat transmission; of air-steam mixtures; and of the flow of air.

A number of very important coöperative investigations are now in progress, the principal expenses of which are aid from funds provided by the coöperating agencies. These include an investigation of the coking of coal in cooperation with Mr. A. T. Hert of the American Cresoating Co.; an investigation of the stresses in railroad track in cooperation with committees of the American Society of Civil Engineers and the American Railway Engineering

Association; an investigation of the stresses in chilled car wheels in cooperation with the Association of Chilled Car Wheel Manufacturers; investigations of problems concerned with coal mining in cooperation with the Illinois Geological Survey and the U. S. Bureau of Mines; an investigation of warm-air furnaces and furnace heating in cooperation with the National Warm Air Heating and Ventilating Association; and an investigation of the fatigue phenomena of metals in cooperation with the Engineering Foundation and the National Research Council. In these coöperative investigations the Engineering Experiment Station provides such laboratory facilities as it may possess, administers the work, and publishes the results obtained; while the cost of special apparatus and other expenses, and the salaries of special investigators, are paid from funds provided for the investigations.

### Description of Laboratory and Equipment

This is one of the largest laboratories of its kind in the country with two main floor levels each approximately 120 by 125 sq. ft. in area, exclusive of two small research laboratories 20 by 27 sq. ft. included in the same building are offices for a staff of from sixteen to eighteen men, three computation rooms, a fairly large lecture room, a stock room, a shop for mechanics and a modern locker room.

The elevated main floor, Fig. 1, carries the principal equipment and is of heavy reinforced concrete construction designed for a working load of 300 lb. per sq. ft. Numerous light and air wells afford communication between this floor and the lower floor, which is of the same area as the main floor, and sufficiently depressed below grade to give a clear working height, in which there are no beams, of 8 ft. 6 in. These features are all shown in Fig. 1. The roof is of the saw-tooth type with three principal bays running east and west.

#### STEAM-ENGINE AND TURBINE EQUIPMENT

The principal prime movers installed in the laboratory consist of six engines and two turbines. There has been installed the following equipment, starting at the west end of this group:

A Chandler and Taylor cross-compound engine (9), made up by connecting a 7-in. by 10-in. and a 10-in. by 12-in. simple throttling slide-valve engine, served by a Deau surface condenser.

A 10-in. by 10-in. Ideal, automatic high-speed, non-condensing engine (10), with balanced slide valve and inertia governor.

A 10-in. by 10-in. Ideal, automatic high-speed, non-condensing engine (14), with a piston valve, and a throttling and centrifugal shaft governor, either of which may be used.

<sup>1</sup>Dean, College of Engineering, and Director, Engineering Experiment Station, University of Illinois. Mem. Am. Soc. M. E.

An 8-in. by 12-in. Meyer automatic engine (13), which operates non-condensing.

An 8-in. by 18 in. simple releasing gear, Murray Corliss engine (15), provided with a Dean surface condenser.

A 12-in. by 24-in. simple double eccentric, releasing gear, Allis-Chalmers Corliss engine (17) belted to a 100-kw. bipolar Edison d. c. generator. This engine has a disk speed-changing device on the governor, whereby the speed may be varied from 60 to 120 r. p. m. A Worthington surface condenser, together with reciprocating wet and dry-vacuum and circulating water pumps take care of the exhaust steam from this unit when the engine is operated condensing.

A Kerr single-velocity stage turbine (16) rated at 60 hp., served by the Worthington surface condenser in case the turbine is run as a condensing unit.

(24), capable of delivering 300 gal. of water per min. against a pressure of 150 lb. per sq. ft., and a De Laval two-stage turbo pump (23) having a capacity of 140 gal. per min. when operating against a head of 300 ft.

#### MAIN STEAM PIPING

The high-pressure saturated-steam line is 8 in. in diameter, and enters the laboratory at the northwest corner. It runs underneath the elevated main floor along the west side for the entire width of the laboratory. Near the middle of the laboratory a connection is made by a long-sweep, vertical bend to the main high-pressure saturated-steam header running the length of the main floor. A separator and reducing valve are installed just after the bend at the point where the pipe again becomes horizontal. The steam pressure

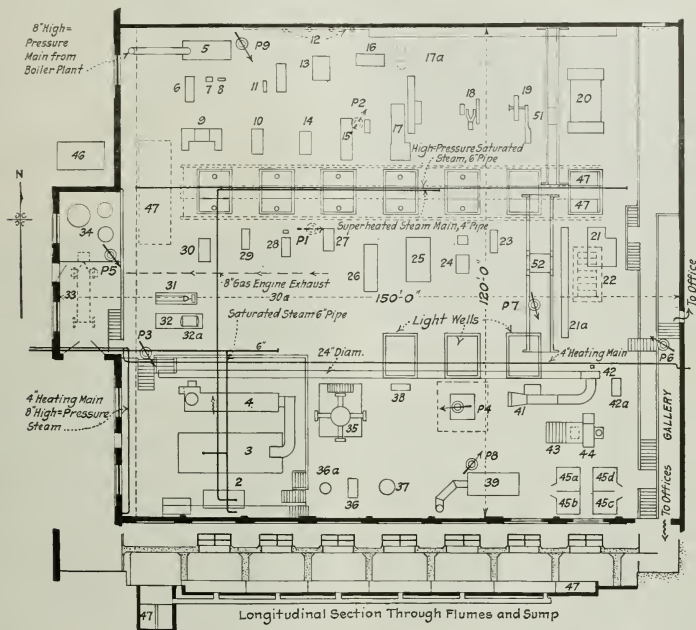

FIG. 1 MAIN FLOOR PLAN OF THE MECHANICAL ENGINEERING LABORATORY SHOWING THE LOCATION OF THE PRINCIPAL EQUIPMENT

A simple slide valve engine (19) designed by Professor Robinson, first professor of mechanical engineering at the University, and built in the mechanical engineering shops of the University.

A large Southwark triple-expansion engine with two direct-current generators (20), given to the University by the Commonwealth Edison Company of Chicago. This machine, formerly installed at the Fisk Street Station of that company, and the preceding unit (19), illustrating the development of the steam engine, will later be placed in a permanent museum.

In the University power house, adjacent to the laboratory, there is available for test work a 100-kw. Curtis turbo-alternator, equipped with the instruments necessary for the measurement of the power output. The turbo-alternator unit has a Wheeler surface condenser, a Wheeler horizontal crank and flywheel wet- and dry-vacuum pump, and a motor-driven centrifugal circulating pump. This condenser equipment is owned by the laboratory.

All engines and turbines, unless otherwise noted, are provided with absorption brakes, either of the Prony or of the rope type.

Equipment for the study of steam calorimeters, the calibration of pressure gages, and the calibration of indicators is located on the north wall (12) and on the adjacent bench.

#### PUMPS

The equipment for test work on pumps consists of a compound Fairbanks-Morse direct double-acting, outside-packed plunger pump

in the steam header is controlled and kept constant by means of the reducing valve.

The piping from the experimental power boiler is so arranged that steam from the boiler may be discharged into the high-pressure saturated-steam main when operating without superheater, or into a second superheated-steam header running parallel to the saturated-steam header and directly underneath it, when operating with superheater. Both saturated- and superheated-steam headers are provided with sliding expansion joints, and are dripped through pot and dump traps.

#### FLUMES AND SUMP

In order to care for the condensed steam discharged from the engines, surface condensers and pumps, two flumes (47) are provided, running nearly the entire length of the basement. The water may be dropped from the flumes through any one of six circular outlets in the bottom of each flume. These outlets discharge into a sump located at the west end of the flumes and underneath the basement floor. This construction is shown by the longitudinal section through flumes and sump. Provision is made for locating V-notch weir plates in the flume so as to measure the amount of water flowing.

At present the water from the sump is discharged to waste by means of an electrically driven centrifugal sump pump. The discharge will eventually be into a cooling tower (46), which is soon to be built.

## SMALL POWER PLANT GROUP

In order to demonstrate the operating characteristics and relation of the equipment of a steam plant, a small power plant has been erected. This plant consists of an Erie City hand-fired portable type of firebox boiler (5), rated at 25 boiler hp. capacity, operating under natural draft with a steel stack 20 in. in diameter, and 40 ft. high; a 7-in. by 10-in. Atlas steam engine (6), with a throttle governor, the output of which is absorbed by a Prony brake; a Cochrane open feedwater heater (7) of 50 boiler hp. capacity; an American single-acting simplex boiler-feed steam pump (8); and a Keystone water meter for measuring the amount of feedwater used.

## POWER BOILER FOR EXPERIMENTAL PURPOSES

The power boiler group (2), (3) and (4), consists of a Heine horizontal water-tube boiler (3) of 210 boiler hp. rated capacity,

FIG. 2 FLUMES, LOWER FLOOR. SEE FIG. 1, P-1

FIG. 3 POWER BOILER GROUP. SEE FIG. 1, P-3

equipped with a Green chain-grate stoker having a grate area of 38.2 sq. ft. and belt driven from a small vertical steam engine; a separately fired Foster superheater (2), having 3400 sq. ft. of superheating surface capable of superheating 4500 lb. of steam per hr. through 200 deg. Fahr., and a Sturtevant economizer and induced-draft fan (4), which draws the flue gases through the economizer when the economizer is being used, or through a bypass underneath the economizer when the dampers are thrown to cut the economizer out of service. The gases are discharged by the induced-draft fan into a steel stack 36 in. in diameter and 45 ft. high. In order to drive this fan, a small vertical Sturtevant steam engine is coupled directly to it. This engine also drives the mechanism for moving the scrapers which clean the economizer tubes.

A feedwater tank (1) is located near the boiler into which tank the feedwater is discharged, after having been measured in a calibrated tank located directly above the feedwater tank. The feedwater can be delivered to the boiler from the feedwater tank either by a direct-acting boiler-feed pump located on the main floor directly

underneath the feedwater tank, or by means of three injectors located directly above the feedwater tank.

The arrangement of the boiler group is such that the operation of the boiler may be studied in any one of three ways: the boiler operating without either the economizer or the superheater, the boiler operating with either economizer or superheater, or the boiler operating with both economizer and superheater.

## HEATING AND VENTILATION

As already indicated, the south bay is largely devoted to work in the field of heating and ventilation. A four-unit steam-radiator testing plant (45-a,b,c,d) has been conveniently arranged for comparing the coefficient of heat transmission of various types of direct steam radiators. Steam can be supplied at any desired constant pressure so that simultaneous tests may be run on the radiators located in the four enclosures, and their comparative efficiencies and transmission coefficients easily determined.

An experimental hot-blast heating unit has been completely equipped for a variety of tests. The heater proper (43) consists of six sections of 1-in. pipe coils, each section containing 507 equivalent lin. ft. of pipe, making a heater equal to approximately 3000 sq. ft. of direct radiation. The condensation from each section can be weighed separately and the air flow and temperature rise measured, so that the effect of any air velocity on the heat transmission coefficient is readily calculated. A Buffalo Forge Company's steel-plate fan (44) with a 100-in.-diameter fan wheel is operated by a direct-connected 6-in. by 6-in. vertical steam engine for drawing air through the unit. Pneumatically controlled bypass dampers control the flow of air through or under the coils.

Near the above heater stands a Warren Webster & Company's

FIG. 4 WARM-AIR-FURNACE TESTING PLANT. SEE FIG. 1, P-4

air washer (41) of the humidifying type. This is equipped for temperature and humidity control with a Powers water thermostat operating on the steam and water mixer in the washer tank. Any desired initial air temperature can be secured by the Vento tempering coil which is under the control of a Johnson Service Company's duct thermostat. The washer has a capacity of 3000 cu. ft. of air per min. at a free-area velocity of 500 ft. per min.

A No. 4 single-inlet Sirocco multiblade fan (42) is used to draw air through the above washer. This fan is mounted on a gallery and discharges the air into a metal duct 24 in. in diameter and 100 ft. long. Complete facilities are provided for making traverses of this duct at any point, so that accurate data on the air volume handled and coefficient of duct friction may be determined. By using the first 40 ft. of the duct and disconnecting the air washer, rating and efficiency tests of the Sirocco fan are easily made. The fan is operated by a Sprague electric dynamometer (42-a) of 10 to 25 hp. capacity with a speed range of from 1000 to 4000 r.p.m.

A heat-transmission testing plant (40) for finding the heat loss through various building materials has been set up in the form of a standard box with special walls 8 in. thick and 6-ft. by 6-ft. sides. An electrical heating element and numerous thermocouples at all surfaces supply and measure heat input and temperature gradients respectively. This plant has been used regularly, but has not yet been inclosed, as indicated on plans, to completely protect it from all disturbing influences.

A Kewanee down-draft brick-set smokeless steam boiler (39) with water-tube grate is the principal item in the heating-boiler equipment. This boiler is rated at 1800 sq. ft. of radiation with a water-grate area of 7.1 sq. ft. It is equipped for securing very complete data on efficiency and capacity, and can be fed with condensation from the hot-blast unit described above. The boiler was given to the University by the Kewanee Boiler Company.

A small Arco cast-iron round steam-heating boiler (37) rated at 800 sq. ft. of radiation is also included in the boiler equipment. This boiler has a grate area of 4.12 sq. ft. and was made by the American Radiator Company. In addition to the above, there is a Mercer cast-iron sectional steam-heating boiler (36) of 1275 sq. ft. rated capacity. This boiler is of the header type with a grate of 6 sq. ft. area, and was made by the H. B. Smith Company. The last two boilers were used in securing data for Bulletin No. 31 on House Heating Boilers.

A single-sweeper vacuum cleaning machine (38), made by the American Rotary Valve Company, has been mounted in portable fashion to facilitate the testing of its efficiency, amount of air handled, and vacuum required for cleaning purposes. The exhaustor is of the rotary, double-impeller type, belted to a 1-hp. motor.

Probably the most elaborate feature of this section of the laboratory is the warm-air-furnace testing plant (35) and its auxiliaries. This equipment has been erected for the purpose of measuring the efficiency and capacity of warm-air furnaces under conditions of service with leaders, stacks and registers at three floor levels. In this way it is not only possible to test the complete system, but also to determine the losses in various parts of a system when in operation.

In order to secure the necessary data, an elaborate system for temperature measurement, using thermocouples, has been worked out so that all readings can be taken at a central point. The air flow is measured at inlet and outlets by specially calibrated anemometers. These anemometers are checked before each test in two calibrating plants which reproduce the conditions of service in all details, such

box has two compartments, each similar to the one used by R. J. Durlin in his experiments in the measurement of air. The machine is equipped with revolution counters, reducing motions and other apparatus requisite for making complete tests.

#### REFRIGERATION EQUIPMENT

The refrigeration plant consists of a York ammonia compression machine (21) and a Vogt absorption machine (21a). A freezing tank, with a capacity of 35 cans, each holding 100 lb., is built into the lower floor, and arranged so that the brine from either machine may be circulated through it for the purpose of making ice. This tank is of waterproof concrete construction, is built flush with the floor level, and is heavily insulated by means of cork blocks.

FIG. 6 HEATING AND VENTILATING EQUIPMENT, SOUTH TO NORTH. SEE FIG. 1, P-8

FIG. 5 THE AUTOMOBILE ENGINE-TESTING PLANT. SEE FIG. 1, P-5

as temperature of air, effect of register faces, movement of anemometer, and velocity of flow. This calibrating system is probably the most unique feature of the tests.

A small auxiliary plant equipped with a single leader and stack has also been set up for studying all types of leader and stack construction. This research work is being carried on in cooperation with the National Warm Air Heating and Ventilating Association.

#### AIR COMPRESSOR

The air-compressor equipment consists of an Ingersoll-Sargent compound steam and two-stage air compressor (25) having a rated capacity of 300 cu. ft. of free air per min. at a speed of 120 r.p.m. The rated delivery pressure is 80 to 100 lb. per sq. in. gage. The air cylinders are 12¼ in. and 18¼ by 12 in. and the compressor is driven by a direct-connected steam engine having cylinders 12 in. and 22 in. by 12 in. The air from this compressor is delivered to a receiver on the lower floor of the laboratory, and from this receiver it is discharged into the atmosphere through a gage box and orifice. This

FIG. 7 MAIN ELEVATED FLOOR, NORTH TO SOUTH. SEE FIG. 1, P-9

The York machine (21) is of the vertical single-acting duplex-compressor type, having cylinders 7½ in. in diameter and a stroke of 10 in. It is driven by a 11½-hp. by 10-in. Corliss engine and has a capacity of 10 tons of refrigeration per 24 hr. A set of cooling coils and a reheater is arranged on the lower floor of the laboratory, thus permitting the refrigeration capacity to be determined without the necessity of making ice, and eliminating the inconvenience of running long tests.

The Vogt machine (21a) has a capacity of 10 tons of refrigeration per 24 hr. It is of the standard commercial type modified slightly to adapt it to testing purposes. There are two anhydrous ammonia receivers equipped with gage glasses, thus facilitating the measurement of the anhydrous ammonia circulated. The piping to the absorber, exchanger, weak-liquor cooler, and rectifier is arranged so that the cooling water may be circulated through them in any way deemed desirable for experimental purposes. The steam used for heating the strong liquor may be taken either from the low-pressure steam main

## BUREAU OF STANDARDS

THE EFFLUX OF GASES THROUGH SMALL ORIFICES, Edgar Buckingham and Junius David Edwards. This paper contains a theoretical discussion of the results of experiments made during an investigation of the effusion method of determining gas density; and it is a sequel to the paper in which that investigation has already been described by one of the present authors. The effects on effusion of viscosity and thermal conductivity of the gas are studied, and formulae for representing these effects are developed and compared with the observed facts. A physical interpretation is thus obtained for the most striking of the apparent anomalies observed in the behavior of gases flowing through very small orifices such as are used in apparatus for determining density of effusion. The mathematical work was, unavoidably, too cumbersome for satisfactory abstraction. The resulting agreement of the theory with the observations is exhibited graphically. It is fairly satisfactory but not perfect, and its imperfections suggest the directions in which further experiments should be made. (Abstract of *Scientific Paper No. 359, U. S. Bureau of Standards, c*)

THE CONSTANTS OF RADIATION OF A UNIFORMLY HEATED ENCLOSURE. Experimental data are given on atmospheric absorption. The paper gives also a recalculation of the coefficient of total radiation of a uniformly heated enclosure, or so-called black body, giving a value of

$$\sigma = 5.72 \times 10^{-12} \text{ watt cm}^2 \text{ deg}^{-4}$$

The effect of atmospheric absorption is discussed, and the conclusion arrived at is that, if corrections are made for atmospheric absorption, the value recently obtained at Naples is close to the average value, viz.,

$$\sigma = 5.7$$

In the second part of the paper the present status of the constant of spectral radiation is discussed. (Abstract of *Scientific Paper No. 357, U. S. Bureau of Standards, by W. W. Coblentz, 1*)

## ENGINEERING MATERIALS

PHYSICAL TESTS OF MALLEABLE IRON. At the recent annual meeting of The American Society for Testing Materials, W. R. Brad, of the Eastern Malleable Iron Co., Nantuxuck, Conn., presented data showing the possibility of making malleable iron in heavy sections.

Test pieces were cut from a malleable-iron bar 3 in. by 3 in. in section. These test pieces ran lengthwise with the bar, and were so selected that every portion of the cross-section was represented.

From data of these tests it would appear that the test pieces from the corners of the bar were the strongest as well as the most ductile, ranging lightly over 45,000 lb. per sq. in. in tensile strength.

The weakest samples were from the center of the bar, but even they gave a tensile strength of 39,859 lb. per sq. in., which is

quite good for iron in the center of such a heavy section of metal.

Data showing the effect of the skin on the strength of malleable iron were also given, and would indicate that there was little difference in minimum tensile strength or other test values before or after machining.

Interesting data are also presented on annealing of cast iron and the effects of carbon contents. (*The Foundry, vol. 47, no. 337, Dec. 15, 1919, pp. 906-908, 6 figs., c*)

## FUELS AND FIRING

### What 18 American Steel Plants Say About Pulverized Coal in Open-Hearth Practice

PULVERIZED COAL IN OPEN-HEARTH PRACTICE, W. H. Fitch. A review of the experience of eighteen American steel plants. From this review it would appear that pulverized coal was applied in some cases deliberately and in other cases under the urgency of necessity, chiefly actual or threatened lack of the fuel regularly used.

Practically all of the furnaces under investigation were designed to use producer gas, though some of them passed to other fuels such as natural gas or fuel oil even before an attempt was made to burn powdered coal.

In some of the cases the results with powdered coal were decidedly unsatisfactory. Apparently this was due chiefly to the lack of proper design of the furnaces, although in the case of acid steel there appeared to be fundamental defects with pulverized coal.

In general, however, the investigation appears to have shown that pulverized coal is quite a proper fuel for open-hearth furnaces, provided only the conditions of its use are right.

In this connection the experience of plants G, H and I is illuminating. During the winter of 1916 there was a scarcity of natural gas, and the management became interested in finding a substitute, fearing the necessary supply of gas would not be obtainable. A careful investigation of the situation was made and an engineering company specializing in this line of work was given a contract to install pulverizing machinery, distributing systems and furnace fixtures.

As it was felt that furnace design was the principal factor in determining the success of operation with a new fuel, it was decided that it would be best to make as little change as possible to begin with, allowing for the result of experience of applying coal dust to one furnace to point the way and nature of changes necessary.

Considerable trouble in various ways was experienced at first, but due to a number of furnaces being in use it was possible to make minor changes at various times when the furnace was down for repairs, and in this way different arrangements of checker brick, ports and roof were experimented with. Changes that could be made easily to the furnace above the charging floor were lim-

ited, due to the necessity of making very radical changes in steel work, which, for the time being, were prohibitive.

Eventually, the slag chamber was found to be a very important factor, as its capacity decided the number of heats that could be made without stopping the furnace for cleaning.

TABLE 1

	Producers	Pulverizers
Power...	75 kw. x 24 hr. x 1 c. \$18.00	122 kw. x 24 hr. x 1 c. \$29.28
Gas and ash man...	18 x 8 x 60 c. .... 86.40	
Dryer man...		3 x 8 x 60 c. .... 14.40
Pulling man...		3 x 8 x 60 c. .... 14.40
Unloading coal...	240 x 2 c. .... 4.80	180 x 2 c. .... 3.60
Repairs...	240 x 10 c. .... 24.00	180 x 10 c. .... 18.00
Steam...	..... 44.40	
Circulating water...	200 gal. per min. .... 4.80	
	182.4	79.68
	\$182.4 + 240 = \$0.76	\$79.68 + 180 = \$0.45

Several other companies have had the same experience with reference to the importance of the proper design of the slag chamber. It appears that the desirable design should embrace a slag chamber of large cubical content, having a removable bottom, and affording the gases an opportunity of expanding and precipitating the heavy oxides of molten ash. Also, there should be a regenerative chamber of large volume and provided with observation and cleaning doors at each end of the furnace, the checker brick being assembled to provide vertical flues of comparatively large area and the waste gases passed through the boiler.

The most economical results, however, are obtained by returning all of the waste heat available to the furnace, and a design of the furnace that will provide for the accumulation and removal of fine ash after passing through the slag chamber will have the effect of cleaning the gases before they enter the regenerative chamber. It will then be possible so to arrange the checker brick to form flue areas that will absorb the maximum quantity of heat from the outgoing gases and permit the incoming live air to be heated to the desired temperature.

There have been accidents and casualties in the use of pulverized coal, but the number is said to have been small and in many instances they were the result of negligence on the part of the operator.

As regards the comparative value of pulverized coal and gasified coal, Table 1 would appear to show that on the whole pulverized coal is cheaper. (*The Iron Age*, vol. 104, no. 26, Dec. 25, 1919, pp. 1323-1328, *gca*)

## HYDRAULIC ENGINEERING

### Proposal to Develop 90,000 hp. from a Tidal-Power Plant in Canada

PROPOSED TIDAL-POWER DEVELOPMENT AT HOPEWELL, N. B. Data of a proposed development of unusually large size to be located at Hopewell, New Brunswick, where it is believed conditions are especially favorable to such an undertaking.

The layout can be seen from Fig. 1, which is a roughly sketched map of the confluence of the Peteticodiack and Memramcook Rivers, which empty themselves into the tidal source, in this case the Shepody Bay.

There are two main dams proposed, the western one 49,000 ft. long and the eastern one 48,000 ft. long, and also a short wing dam of 900 ft. dividing the high-level from the low-level basins. It is proposed to have a highway and trolley line running over these dams to facilitate shore-to-shore communication.

The western dam would be provided with automatic flap gates opening upstream, which would allow the high-level basin to be filled at each high tide, and at the eastern dam there would be similar gates opening downstream to allow the low-level basin to empty on every ebb tide.

The cycle of operation beginning with low tide would be as follows: The water from the spillway would be discharged directly into Shepody Bay, which is the tidal supply, with the gradually

decreasing head as the tide rises. At the proper time the attendants close these gates and open other gates, allowing the spillway discharge to enter the low-level basin, into which the spillway will continue to discharge for about 6½ hr., that is, through the last 3½ hr. of flood tide and through the first 3 hr. of ebb tide, after which the cycle will be reversed and start all over again. During the flood tide the high-level basin is replenished and by this means continuous 24-hr. operation is secured.

In order to determine the commercial possibilities of a given location for tidal-power generation, it is the range of the tide and not the actual rise which has to be considered, and to determine this an analysis of the ranges which will occur in the course of a year is necessary. At Hopewell about 15 per cent of the time the tides exceed 42 ft. range, and for about the same percentage of time there are sub-normal neap tides ranging less than 32 ft.

The initial installation is proposed to be about 90,000 gross hp., for which it is believed there is ample water available. By steady

FIG. 1 LAYOUT OF THE PROPOSED TIDAL-POWER PLANT AT HOPEWELL, NEW BRUNSWICK

ly improving the ratio of the two basins, it is believed that the power output could be increased up to 200,000 hp. without making the level drop exceed the limit of 6 in. per hr. (*The Electrical Times*, vol. 56, no. 1469, Dec. 11, 1919, pp. 462-463, 2 figs., d)

## LUBRICATION

### The Physico-Chemical Phenomena Governing Lubrication

#### OILINESS OF LUBRICANTS—WHAT IT IS AND WHAT IT DOES

LUBRICATION. Abstract of a discussion on this subject before the Physical Society, London, in connection with a paper by R. Mountford Deley on Oiliness and Lubrication.

The significant feature about this discussion is the large attention paid to the physico-chemical phenomena in connection with lubrication. In introducing the discussion, Dr. F. E. Stanton gave a brief account of the history of the physics of lubrication from the researches of Beauchamp Tower in 1833 to the work of Somerfeld and A. G. M. Michell and the later investigations of Harrison and Hyde.

An abstract of Deley's paper will be given later. Among available data it appears that it presents a description of the apparatus used for testing oiliness at the National Physical Laboratory at Teddington, and data obtained therewith.

In discussing this paper L. Archbutt pointed out that the following two conditions should be clearly distinguished in considering lubrication problems: (1) Cases where the two solid surfaces were completely separated by a film of oil as with properly fitted journals revolving at high speed and abundantly fed with oil; and (2) cases where owing to the shape and condition of the surfaces, low speed, high pressure or inadequate oil supply, the oil film could not form completely or became broken so that the solid surfaces came into contact.

In the first instance the friction was entirely due to the viscosity of the oil and the theory of Reynolds and the study of physical and chemical characteristics of an oil could be used as guides. In the second case the circumstances were entirely different and trials had to be relied on. Oils alike in viscosity might have different friction-reducing values and it is here that the property termed "oiliness" becomes very important.

Mr. Deeley's machine seems likely to give a means of measuring that oiliness and his view that oiliness enables the oil or some constituent of it to combine with the surface and form a lubricating film is in accord with Langmuir's view.

L. Archbutt recently found that under the same conditions of speed and pressure and with the same oil, bearings of white metal would carry double the load of bronze bearings without increase of friction.

On Langmuir's theory the molecules of the oil and solid were held together by residual or secondary valencies, and the more chemically active the lubricant, the more firmly it would be attached.

In this connection, the behavior of acids in lubricants is quite significant. Free acids have so far been considered injurious in lubricants, because they corroded and formed soaps thickening the lubricant in the presence of moisture.

Sonthome found, however, that the very restricted amount of fatty acids, while of no advantage in the first of the two cases above referred to, had a very remarkable effect in the second of the two cases, that is, the one in which the surfaces of journal and bearing come into contact.

Experimenting with a Thurston machine at low speed, 7 ft. per min., and pressure of 270 lb. per sq. in., Mr. Archbutt had found that 1 per cent of the fatty acid of rape oil added to a mineral lubricant lowered the coefficient of friction from 0.0047 down to 0.0033, and that 2 per cent of the acid did not effect any further lowering. Of neutral rape oil 60 per cent was required to produce the same effect; it was in that respect rather fortunate that commercial rape oil always contained some fatty acid. The important point was that a small percentage of fatty acid improved the lubricating power of a mineral oil as much as a large percentage of fatty oil. But it was also noteworthy that he had found a perfectly neutral rape oil to give lower friction than a mineral oil of the same viscosity. In comparative tests made with a commercial rape oil of 2.4 per cent of fatty acid  $R$ , with a perfectly neutral oil  $R$ , prepared from  $R$ , and with a mineral oil  $M$  of the same viscosity, he had obtained the following friction coefficients:  $M = 0.0078$ ,  $R = 0.0050$ ,  $R_1 = 0.0045$ . These results, if confirmed, would suggest that the oiliness or lubricating efficiency of the unsaturated molecules of the neutral rape oil was nearly as great as that of the free fatty-acid molecules, but that the acid molecules were much more active in their influence on the hydrocarbon molecules of the mineral oil. The size of the molecules and the thickness of the molecular layer would be important factors, and Langmuir's researches, referred to in an earlier paragraph, seemed to throw considerable light upon the subject.

Dr. H. S. Allen, of Edinburgh University, in a note on Molecular Layers in Lubrication, again referred to Langmuir's theory of films. This theory might be expressed in its application to lubrication as follows: The metal covers itself with a layer of oil one molecule thick resembling a piece of velvet firmly glued to the metal with the pile outward, and two such velveted surfaces would glide over one another with but little friction. If this be so, oiliness would depend neither on viscosity nor on compressibility, but on chemical forces and on the nature of both the lubricant and the metallic surface.

B. W. Hardy emphasized the highly complex nature of the phenomena of lubrication, especially the chemical problems connected with the mixing of substances of different lubricating powers.

J. E. Southcombe told of his experiments with the object of finding out in what respect the fatty oils differed from mineral oils. An abstract of his remarks will be given at a later date. (*Engineering*, vol. 108, no. 2814, December 5, 1919, pp. 758-760, a)

## MACHINE PARTS

### Improved Worm Gear Having Efficiency of Over 97 Per Cent

DAVID BROWN & SON IMPROVED WORM GEAR. Description of a worm gear developed by a British concern. It is stated that in a certified test made at the National Physical Laboratory, Teddington, England, an efficiency of over 97 per cent was secured.

The illustrations (Fig. 2) show the details of the character and area of contact in the new F. J. gears. The view on the left shows the worm in such a position that the drive is taken by the three threads,  $A$ ,  $B$ , and  $C$ , while that on the right shows the worm in a different position, having been rotated through an angle of 45 deg., with the result that the two threads  $A$  and  $B$  are in simultaneous contact with the worm wheel. The area in dotted outline across the teeth of the worm marks the zone of contact between the gears when the worm is rotated in the direction indicated in the end view. The intersections of the worm threads and the zone give the lines of contact between the worm and wheel teeth, and at no point outside this zone is there any contact between worm and wheel. It is this contour of the zone of contact that was arrived at by the mathematical calculation previously referred to, and which was submitted to Faraday House.

In the left-hand view, the actual contact between the worm

FIG. 2 ZONE OF CONTACT BETWEEN THE F. J. WORM AND WHEEL

thread  $A$  and the wheel is marked by the dotted line 1-1A, that between the worm thread  $B$  and the wheel by the line 2-2A, and on the worm thread  $C$  by the line 3-3A. In the right-hand view the worm has been rotated through an angle of 45 deg., the new line of contact being again shown dotted, only in this case the worm thread  $C$  has passed beyond the zone of contact and has thus ceased to make contact with the worm wheel.

The illustrations (Fig. 3) show the zone of contact for a four-threaded worm of the ordinary shape in which the teeth of the worm are straight-sided in section; that is to say, in the form of a rack. As the linear section of this type of worm corresponds to a straight-sided rack, and as the straight-sided rack forms the basis of the involute spur gear, this shape of worm is generally known as the involute worm. As before, the zone of contact is shown in dotted line, but in this instance two teeth only are in contact in the left-hand view— $A$  and  $B$ —giving lines of contact 1-1A and 2-2A, while in the right-hand view the tooth  $A$  carries the entire load along the line of contact 1-1A. The unsymmetrical contour of the zone of contact will also be observed. More noticeable still is the difference between the irregular lines of contact shown on the end views of the involute worm as compared with the symmetrical lines of the F. J.

It must be understood that in both cases whenever the worm is revolved through an angle of 90 deg., the line of contact 1-1.4 will sweep across the zone of contact until it takes up the position marked 2-2.4, because when a four-threaded worm is moved a quarter of a revolution (or 90 deg.), the thread *A* will naturally take up the position of the thread *B*. In the F. J. system it will be seen that the point 1 at the root of the worm (end view) falls into the position 2 after a quarter of a revolution; that is to say, the actual contact travels in the same direction as the worm through a distance of approximately 50 to 60 deg., hence about two-thirds of the motion is transmitted by a rolling action and only one-third by sliding. This means that a rolling action is introduced between the teeth of the gears, thereby reducing the ordinary rubbing velocity to a minimum. Thus the gear teeth, instead of rubbing against each other at, say, 1000 ft. per min., really only rub at the reduced speed of about 350 ft. per min., this being due wholly to the rolling action of the F. J. tooth contact.

This is not so on the involute worm-gear system. In the left-hand view in Fig. 2 the point of contact 1A actually moves in the opposite direction to the rotation of the worm to the point 2A, thereby giving the rubbing velocity even more than its full the-

FIG. 3 ZONE OF CONTACT BETWEEN THE ORDINARY WORM AND WHEEL

oretical value, while rolling action, at the ends *A* of the lines of contact, is absolutely non-existent.

A peculiarly inefficient characteristic of the involute system is that the extremities of the lines of contact (see plan view of worm) travel from positions 1 and 1.4 toward each other until they meet, and vanish just beyond the points 2, 2.4, as shown in the left-hand plan view (Fig. 3).

The plan view of the F. J. system (Fig. 2) shows the points *A* always moving from left to right, in the same direction as the rotation of the worm, while the left-hand plan view of the "involute" system shows the point *A* moving very slightly from right to left, actually against the rotation of the worm. The high rubbing velocity which occurs on the points *AA*, together with the converging lines of contact which induce a concentrated load, all tend to produce the worst possible conditions on the leaving side of the worm wheel. This explains the well-known fact that when a worm gear of the "involute" type is overloaded, "pitting" first takes place on this side of the wheel, and on this side only, while those portions of the teeth on the entering side of the wheel remain unmarked. (*The Automobile Engineer*, vol. 9, no. 133, December 1919, p. 449, 2 figs., d)

### Tests on Best Speeds, Fits and Settings of Lathe Turning Tools

CUTTING POWER OF LATHE TURNING TOOLS, George W. Barley. In November 1913 Prof. W. Ripper and the present author read a paper under the same title as the present one before the Institution of Mechanical Engineers. The present article is a continuation of that article and deals with experiments made with lathe turning tools and in particular with such matters as relation between the cutting speed and the degree of finish obtained by the use of ordinary lathe finishing and light cutting tools and the influence of the various factors in tool design and position on the cutting power of the tools, power consumption, etc.

The paper, while of great interest, is too extensive for a detailed abstract. Because of this only the conclusions arrived at by the author are reproduced.

1. That there is no practical cutting speed below which it is impossible to obtain a satisfactory surface on plain-carbon steels by means of ordinary lathe finishing tools, whether these be made of plain carbon tool steel, ordinary (non-vanadium) high-speed steel, or superior (vanadium) high-speed steel. There is, however, a maximum limiting speed at or above which a satisfactory finish cannot be obtained on account of the tendency of the tool to pluck at and tear the surface, this tendency being related to the phenomenon of building up on the cutting edge of the tool. For the finishing of mild steel this limit is not very different from each of the above three varieties of tool steel and is within the range of 48 ft. to 58 ft. per min. For the finishing of hard steel this limit does depend somewhat on the variety of tool steel employed and is within the range of 23 ft. to 28 ft., 17 ft. to 21 ft., and 28 ft. to 34 ft. per min. for the three varieties, respectively.

2. The durability or life of a lathe finishing tool, whether of plain carbon or high-speed steel, is for all cutting speeds below the limiting speed some function of the reciprocal of the cutting speed; in other words, an increase in the cutting speed below the limiting value is always accompanied by a decrease in the life or durability of the tool.

3. The most suitable angle of side rake (that is, the angle of side rake associated with maximum durability and cutting power) for a high-speed lathe roughing tool working on steel depends upon the physical properties of the steel. For mild-steel turning it lies between 20 and 25 deg., while for hard-steel turning it is of the order of 10 deg.; and if these angles are either increased or reduced there is always a depreciation of cutting power.

4. The color of the turnings formed by a high-speed lathe roughing tool when working on steel is not necessarily a true index of the condition of maximum cutting efficiency. Thus, in the case of hard-steel turning, the turning color which is associated with maximum cutting efficiency is a pale blue, while a mild-steel turning which is removed under the conditions of maximum efficiency is practically uncolored, apart, of course, from the natural gray color of the steel.

5. The net power consumption of a high-speed roughing tool is dependent, other conditions being constant, upon the amount of top rake on the tool, the relation between these two quantities being reciprocal in character, so that, within the limits of ordinary practice, a reduction in the top-rake angles of a tool is always accompanied by an increase in the net amount of power consumed. The law connecting the variations of the two quantities appears to be of the nature of a straight-line law for all qualities of steel machined. There are, therefore, no critical values of the rake angles in regard to power consumption as there are in regard to durability and cutting power.

6. The cutting power of a high-speed lathe tool is influenced by both the cross-sectional area of the shank of the tool and the nose radius, but the influence of the latter factor very largely predominates in all cases. Thus with a number of different sections of tool steel, an increase of the nose radius of 100 per cent produced an average increase in the cutting power of 45 per cent; whereas an increase of the cross-section of the shank of the tool of 500 per cent with a constant nose radius produced an average increase in the cutting power of only 8.5 per cent.

7 The effect of raising a roughing tool so that its cutting edge is slightly above the horizontal plane passing through the lathe centers is, generally, to increase the cutting power of the tool slightly and to reduce its net power consumption slightly, when compared with its normal position, that is, with its cutting edge at the same height as the lathe-center axis.

8 Forging the nose of a lathe cutting tool does not materially affect its cutting power and durability, there being practically nothing to choose between a completely ground tool and a forged and ground tool, otherwise identical.

9 The general direction and the active length of the cutting edge of a high-speed tool have a slight influence upon the net power consumption of the tool, the influence being such that, with any given depth of cut, if the active length of the cutting edge is increased by an alteration of the general direction of the edge, the net power consumed is increased under conditions of working otherwise identical.

10 There is no marked difference in the net amounts of energy required per cubic inch of material removed from mild-steel and hard-steel bars at high and low cutting speeds.

11 The increase in the cutting power of a high-speed roughing tool resulting from the use of a given stream of water as a cooling agent is greater with small cuts than with heavier ones, indicating that, with heavier cuts, heavier flows of coolant should be used. The velocity of flow of a stream of coolant does not very materially affect the improvement in the cutting power of a tool due to the use of the coolant, provided that the velocity is not such as to cause excessive splashing of the coolant.

12 The cutting efficiency of a high-speed roughing tool depends very largely upon the condition of the cutting edge of the tool,

opening, as indicated at *C*, Fig. 4. This opening is made by means of a diamond chip held by hand between the points of a pair of long-nosed pliers. After the conical hole has been cut, the drilling operation is started by means of a tool carried in the spindle of the machine, which is so designed that the table rotates and also has a vertical reciprocating motion imparted to it.

After the hole has been drilled about three-quarters of the way through the diamond, as indicated at *D*, the work is removed from the machine and turned over, after which it is reset and the conical opening is cut in the opposite side of the diamond, as indicated at *E*. Of course, this second conical opening has to be located exactly opposite the hole which has been drilled in the work. The next step is to drill from the bottom of this conical opening to make a connection with the hole entering the stone from the opposite side, *F*. It is very important to have the inside of the die absolutely smooth in order to prevent forming seams in the work and also to have the bell mouth of the die formed in such a way that the metal will pass into the die without undue frictional resistance. This is done by giving the die the shape shown at *G*. The inlet to the throat of the die is made slightly larger than the outlet at the back, which requires a great amount of dexterity to do. The dies are set in brass mounts.

The feature of diamond dies which makes them more economical in use than steel, cast iron or other comparatively inexpensive materials, is that they give a far greater amount of service before the tool is worn out, because of the extreme hardness of the diamond. This resistance against wear is also the means of maintaining greater uniformity in the diameter of the wire that is drawn through the die.

The time comes, however, when the die becomes too large to

FIG. 4 ROUGH DIAMOND (A) AND THE CROSS-SECTIONAL VIEWS SHOWING SUCCESSIVE STEPS IN THE PROCESS OF MAKING WIRE-DRAWING DIES

and though a tool with its cutting edge blunted in the cutting process may continue to cut, it cannot be used in that condition for the purpose of starting a new cut. (Paper before the Institution of Mechanical Engineers, Dec. 19, 1919, *Journal of the Institution of Mechanical Engineers*. Compare also *Engineering*, vol. 108, no. 2817, Dec. 26, 1919, pp. 867-875, 91 figs., *et al.*)

## MECHANICAL PROCESSES

### Diamond Dies and How They Are Made

MAKING DIAMOND WIRE-DRAWING DIES, Edward K. Hammond. Diamond dies are extensively used for drawing small wire made of all kinds of metals and for sizes from 0.08 in. down they are used practically exclusively. Because of this the following data as to the manufacture of such dies by the Vianney Wire Die Works at Trevoix, France, become of interest.

For the manufacture of dies diamonds are used which are of a grade unsuitable for use in jewelry.

The firm standardized the size of diamonds from which dies of different diameters are made, the diamonds themselves ranging from one carat to sizes as large as twenty carats.

As is generally known, the diamond is so hard that it can be cut only with another diamond or diamond dust. The first step is the flattening of a rough stone, which is done with laps charged with diamond dust made by pulverizing small-sized diamonds or chips from larger stones and then grading the dust by sifting it through sieves with various numbers of meshes per square inch. This is succeeded by several operations, comprising the cutting of the die opening. The first step is to chuck the diamond on the faceplate of a special drilling machine and cut a conical-shaped

produce wire that comes within the specified limit of tolerance. When this point has been reached the die is recut for a larger size, which is done by the use of a steel lapping tool charged with diamond dust. In connection with this operation the bell-mouthed opening must again be carefully finished to bring it tangent to the new throat which has been cut in the die and the inner surface must once more be carefully polished. The original article illustrates the special type of lathe used for refinishing diamond dies. (*Machinery*, vol. 26, no. 3, Nov. 1919, pp. 264-266, 5 figs., *d*)

## MECHANICS

### French Tests on Longitudinal Internal Stresses in Rapidly Cooled Steel Cylinders

INFLUENCE OF VARIOUS FACTORS ON THE RISE OF LONGITUDINAL INTERNAL STRESSES DUE TO RAPID COOLING OF STEEL CYLINDERS, M. Portevin. The longitudinal internal stresses were determined by measuring by means of a comparator the change of length which accompanied the removal in a lathe of concentric layers of metal on the cylinder.

The necessity of keeping the test pieces in a state of easy machining limited the initial temperatures of rapid cooling to the lower point of transformation of steel, which is around 700 deg. cent. (1292 deg. Fahr.) in order to avoid the hardening which would follow other treatment.

The internal stresses were computed by using the formula of Heyn and Bauer. If  $l$  and  $l_n$  are the initial length of a test and its length up to the removal of the  $n$ th layer,  $S_n$  the area of a straight section remaining after the removal of the  $n$ th layer, and

$E$  the modulus of elasticity of the metal, then the stress  $f_n$  which was initially present in the  $n$ th layer is

$$f_n = \frac{E}{1} \frac{S''_n(l_n - l) - S''_{n-1}(l_{n-1} - l)}{S''_{n1} - S''_n}$$

For a given steel the internal stresses produced by rapid cooling are a consequence of the lack of isothermic condition of the mass, that is, of instantaneous inequality of distribution of temperatures during this operation. These variations of temperature at various points of a metal cylinder cooled by immersion into a liquid vary with the temperature of immersion, the external conditions of cooling and the diameter of the cylinder. In particular, the external conditions of cooling depend on the nature of the cooling liquid, its temperature and the duration of the immersion.

In the present instance the author investigates in a quantitative manner the results obtained by varying separately these different factors. The numerical results of the same investigation will be published separately.

**Temperature of Immersion.** The internal stresses rise very rapidly with the temperature of immersion when this latter increases from 200 deg. cent. (392 deg. Fahr.) to 600 deg. cent. (1112 deg. Fahr.). They are practically nil for temperatures below 200

degrees, respectively, 1.5, 3.5, 8 and 13 sec., there was a net increase in the internal stresses for the case of cylinders immersed in the water at a temperature of 650 deg. cent. (1202 deg. Fahr.). This is also apparent for the range of temperatures between 8 sec. and 13 sec., although by interpolating results of previous tests it may be estimated that beginning with 5 sec. the axial temperature falls below 300 deg. cent. (572 deg. Fahr.). Fig. 7 gives the internal stresses as a function of the square of the distance from the axis for a semi-hard steel cylinder.

**Diameter of the Cylinder.** Tests carried out on semi-hard steel cylinders of 20 mm., 35 mm., 50 mm. and 60 mm. (0.7 in., 1.37 in., 1.96 in., 2.36 in.) in diameter, respectively, have given results in which the anomalies are apparently due to experimental errors, but which nevertheless indicate the decrease of internal stresses with the diameter, a decrease, it may be remarked, which is really not very rapid.

A knowledge of these results was necessary for clearing up the entire problem of tempering of steel. (Etude de l'influence de divers facteurs sur la création des efforts internes longitudinaux lors du refroidissement rapide de cylindres d'acier. *Comptes Rendus hebdomadaires des Séances de l'Académie des Sciences*, vol. 169, no. 21. Nov. 24. 1919, pp. 955-957, 3 figs., cA)

FIG. 5

FIG. 6

FIG. 7

FIG. 5 VARIATION OF INTERNAL STRESSES IN RAPIDLY COOLED STEEL CYLINDERS AS A FUNCTION OF THE TEMPERATURE OF IMMERSION. FIG. 6 VARIATION OF INTERNAL STRESSES IN RAPIDLY COOLED STEEL CYLINDERS AS A FUNCTION OF THE TEMPERATURE OF THE WATER. FIG. 7 VARIATION OF INTERNAL STRESSES IN RAPIDLY COOLED STEEL CYLINDERS AS A FUNCTION OF THE DURATION OF IMMERSION

deg. cent. (392 deg. Fahr.) and the diagram of Fig. 5 gives for a steel cylinder the curves of internal stresses as a function of the square of the distance from the axis.

For reasons given above (necessity of keeping the metal machinable) the tests were not carried to higher temperatures, but in view of the viscosity of steel at high temperatures no material increase of internal stresses was to be expected.

**Nature of the Cooling Liquid.** Comparison of internal stresses arising through immersion in water and in oil at a temperature of 650 deg. cent. (1202 deg. Fahr.) shows that in the latter case they are from two to four times smaller than in the former, according to the character of the steel and according to whether we consider the peripheral stresses of compression or the axial stresses of expansion.

**Temperature of the Water.** The internal stresses decrease with the temperature of the water and become practically nil for a temperature of 100 deg. cent. (212 deg. Fahr.). The curves of Fig. 6 indicate this variation for a hard steel. It is found that when the temperature of the water is increased by 12 to 25 deg. cent. (21.6 to 45 deg. Fahr.) a reduction of internal stresses is observed, small but unnoticeable, and in addition the internal stresses lose a good deal of their regularity, that is, they cease to maintain materially the character of revolution around the axis of the cylinder.

**Duration of Immersion.** In tests where the duration of im-

### Description of Modern Methods of Making Puddled Iron

**Puddled-IRON PRACTICE,** J. E. Fletcher. There has been a material revival of interest in puddling iron. Hall's process lies at the root of present and future puddling processes and is not likely to be superseded. It is conceivable that further attempts may be made to produce wrought iron directly from poorly silicious ores or by the decarburization of cheaply produced mild steel, but there are fundamental difficulties in the way of success affecting the character of the crystalline structure and the related welding and fibering properties of the resulting product.

There are three factors in puddling that affect the entire situation. These factors are:

- 1 The puddling furnace as we now know it is one of the most wasteful of metallurgical furnaces, using more fuel per ton of product than any other continuous process.
- 2 The labor cost per ton is abnormally high as is also the cost of furnace upkeep.
- 3 The rolling, shingling and material handling and transport plants are usually crude and excessively wasteful in power cost per ton of product.

The writer vigorously criticises the design of coal-fired puddling furnaces, claiming that the radiation losses in such a furnace and its waste-heat boiler amount to at least 20 per cent of the heat

energy of the coal burned or equivalent to, say, 560 to 784 lb. per ton of puddled-iron heat, whereas in the steel furnace the radiation losses do not exceed 224 lb. per ton of steel cast.

The radiation losses in a puddling furnace per unit of metal charged average from 10 to 15 times as much as in the open-hearth steel furnace, and so on.

On the whole, the author comes to the conclusion that the small furnace used in puddling is a real obstacle to fuel economy as its relatively large hearth causes the excessive radiation areas.

The construction and proportions of the modern puddling furnace are not likely to be substantially altered or improved, but it is possible, to improve the grate and firebox and to provide

also been suggested and a furnace was built with a small producer at the firing end.

The process of puddling covers three stages, namely, the melting stage, occupying 30 to 40 min. depending on the class of pig iron used and the efficiency of the fuel; the boiling stage, occupying 30 min.; and the drying and haling, followed by fettling and charging periods, occupying about 40 min.

It appears further that the melting period demands, under the present conditions, from a little over 5000 lb. to close to 6000 lb. of coal per ton of metal melted and is the most wasteful stage of the puddling process.

Cupola melting which would be more economical as far as fuel consumption goes is not suitable as it yields a higher-carbon metal and very little reduction of the remaining metalloids, and because of this the boiling period in the puddling furnace is lengthened.

The author proposes a special method of procedure based on manipulation of the slags with a view to producing a low-sulphur metal from the cupola described in the original article.

The characteristic feature of the new process is the addition of manganese at a certain stage which causes a delay in the elimination of the carbon, while it accelerates the elimination of silicon and phosphorus. A liquid slag resulted and the metal poured flows easily and is well deoxidized.

The author also proposes the design of a plant consisting of an open-hearth tilting or fixed basin-lined furnace, the waste heat from which is used in attached efficient boilers fitted with auxiliary fuel-supply apparatus, this latter having the purpose of increasing the steam requirements during the charging and tapping stages. From the open-hearth roughing furnace the metal is ladled to mechanical puddling furnaces fired with pulverized coal and having waste-heat boilers attached to them.

Each of the units composing the proposed plant are at work. The open hearth furnace is regularly melting iron on a pulverized-coal consumption of 448 to 560 lb. per ton of iron melted. Puddling furnaces similarly fired are operating on a consumption of 1300 to 1600 lb. per ton of puddled bar, when dealing with cold pig iron. When puddling molten charged material the coal burned should not exceed 800 to 1000 lb. per ton of product, six furnaces doing the work of the present ten.

If the roll trains and shingling machines or squeezers be operated by electrical power, and they can be, it is conceivable, that, given cheap electrical energy, such a combination of the duplex system with mechanical puddling furnaces and with electrical rolling and shingling equipment should furnish the most economical puddling plant possible. (Paper before the Staffordshire Iron and Steel Institute read Nov. 22, 1919, abstracted through *The Iron Trade Review*, vol. 66, no. 2, Jan. 8, 1920, pp. 152-156, 4 figs. *dg*)

## PHYSICS

ABSOLUTE UNIT OF TIME BASED ON NEWTONIAN LAWS, Gabriel Lippmann. The unit of time in general use, namely, the second, is an arbitrary and not an absolute unit. It is a submultiple of the solar day and can be obtained only by astronomic observation. If some fabulous being flew over from the solar system to Sirius, he would have lost the second on the way, at the instant when the earth's system disappeared from his sight. On the other hand, if the same being had some formula to express an absolute unit of time, he could reconstruct this unit no matter in what part of the world's system he might happen to be. In physics the use of the absolute unit is, however, of quite a practical value in that it permits the elimination of arbitrary numerical coefficients. Such coefficients are inconvenient in that they complicate the form of equations, introduce a possible source of error, and, what is still more important, in numerical computations tend to conceal the nature of relations existing between phenomena of different character. Without absolute units it would have been very difficult to create the electromagnetic theory of light, for example. It is therefore very desirable to secure a definition of a unit of time in absolute measurements.

The present author builds up an absolute unit of time on the

FIG. 8. END ELEVATION OF FURNACE ARRANGED FOR EASY REMOVAL OF ASHES

efficient means for burning the poorer coals—in particular, to reduce the amount of unburned fuel that goes into the ashpit. Figs. 8 and 9 show sections of a furnace arrangement designed by the author.

The grate consists of a series of tubular bars perforated for air action, over which a number of specially shaped chilled cast-

FIG. 9. SECTION THROUGH FURNACE SHOWING ARRANGEMENT OF GRATES

iron disks are threaded. These form a kind of roller grooved longitudinally, so that when it is rotated it causes clinkers to crack and burned ashes accumulated in the troughs between the roller bars to roll into the ashpit.

The air required for combustion is forced through the tubes by steam jets and passes out through the perforations into the fuel bed and ashpit which is closed by the front plate of the ash-removal car. The air ducts between the grate disks are nozzle-shaped and the grates can be cleaned without opening the doors. Large clinkers can be removed through the large holes provided above the grate in the firebox back plate.

The application of gas firing to small puddling furnaces has

basis of the Newtonian theory of gravitation. In accordance with this theory

$$f = k \frac{mm'}{r^2} \dots \dots \dots [1]$$

where  $f$  is the static force of attraction between masses  $m$  and  $m'$  at a distance  $r$  from each other, and  $k$  is the Newtonian coefficient of attraction, the numerical value of which depends on the units of measurement selected, which may be such that  $k = 1$ . By this the unit of force is determined: It is the attraction which exists between two masses, each of which is equal to unity, separated by a unit of distance.

Hence, if we call  $\gamma$  the intensity of the Newtonian field due to a mass  $m$  at a distance  $r$ , we have  $f = \gamma m'$ , and hence

$$\gamma = \frac{m}{r^2} \dots \dots \dots [3]$$

Hitherto only static forces were considered and the element of time was absent.

But let us consider now the acceleration given to mass  $m$  by the force  $f$ , assuming that the force is equal to the product of mass by acceleration. We have then

$$\frac{m}{r^2} = \frac{d^2 r}{dt^2} \dots \dots \dots [4]$$

where the value of the second member depends on the unit of time employed; conversely, Equation [4] defines the unit of force employed as the first member of the equation is completely defined. We may therefore write

$$\gamma = \frac{d^2 r}{dt^2} \dots \dots \dots [5]$$

The unit of force is therefore such that the acceleration is numerically equal to the intensity of weight, or the acceleration is equal to unity in a gravitational field equal to unity.

We may now calculate the dimensions of the absolute time

We have to admit in the usual manner that the mass is measured by the product of a volume  $L^3$  by density  $\rho$ , this latter being taken for a substance of such type of water. Equation [4] becomes then

$$\frac{\rho L^3}{L^2} = \frac{L}{\theta^2} \dots \dots \dots [6]$$

Hence

$$\theta = \frac{1}{\sqrt{\rho}} \dots \dots \dots [7]$$

The absolute time is therefore a zero dimension in reference to lengths, which means that a unit of time is independent of the choice of units of length and is the same in the centimeter-gram system or the meter-ton system, or even the foot-cubic-foot system. As regards the coefficient  $\rho$ , it has to be considered only if we wish to attempt to replace water as a typical substance by some other substance. For example, if we should desire to replace by mercury, the factor  $\sqrt{\rho}$  would be equal to  $\sqrt{13.6}$  and the unit of time would be  $\sqrt{13.6}$  times greater.

The author discusses in detail the methods of introducing this absolute unit of time into various physical computations. (*Annales de Physique*, 9th series, vol. 12, Sept.-Oct., 1919, pp. 226-237, t)

## RAILROAD ENGINEERING

**RIKPEN AUTOMATIC DRIFTING VALVE FOR LOCOMOTIVES.** Description of a drifting valve which is operated by the compression in the cylinder, known as the Ripken valve, and in use on the Minneapolis, St. Paul and Sault Sainte Marie Railroad.

The valve comes into operation before the cylinders are emptied of steam pressure after the throttle has been closed and is kept in operation and furnishes the needed amount of steam until the pistons cease to move. It is automatically closed just as the engine stops by the building up of pressure in the steam chest.

Only one valve per engine is used as the steam is passed directly to the branch pipe or the saturated end of the superheater header. This arrangement is advantageous as it reduces the amount of

steam required and also protects the superheater elements against overheating. It makes unnecessary the use of either air relief valves or bypass valves.

The original article illustrates and describes the construction of the valve, which is, however, well known generally. It also gives a series of indicator cards from an engine fitted with the Ripken valve, shown in Fig. 10.

Tests on a superheater locomotive with 25-in. by 26-in. cylinders supplied with steam from a 2-in. pipe showed that the valve when adjusted between 25 and 30 lb. pressure in the steam chest at 25 per cent cut-off at a speed of 60 miles an hour, prevented the formation of harmful vacuum even at such high speed. After a shut-off with the reverse lever in running position, the valve would open when the steam-chest pressure rose to 49 lb., which

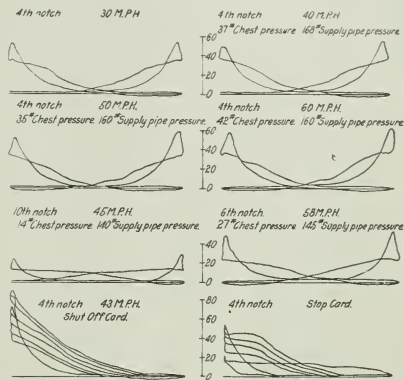

FIG. 10 TYPICAL INDICATOR CARDS FROM A LOCOMOTIVE ENGINE FITTED WITH THE RIKPEN AUTOMATIC DRIFTING VALVE

occurred just before the stop, allowing time for the superheater to empty itself before the engine came to rest. (*Railway Age*, vol. 67, no. 22, Nov. 28, 1919, pp. 1079-1080, 2 figs., de)

**USE AND HANDLING OF FUEL OIL.** A. M. Schoen. Paper presented before the Railway Fire Protection Association Convention at Chicago in November 1919, at the same time as the Report of the Committee on Oil-Burning Appliances, B. S. Mace, Chairman.

The Report of the Committee contains specific rules and requirements for the storage and use of fuel oil and for the construction and installation of oil-burning equipment.

A. M. Schoen's paper called attention to the fact that while oil has been used for locomotives in the West and on the Florida East Coast for a number of years, there would appear to be no well-defined standards accepted, and even the individual railroads appear to consider this fuel as not yet entirely permanent. It seems, however, to be time to formulate standard specifications in an advisory form, at least, that may be adopted by railroads preparing to adopt oil as fuel.

Not enough attention is being paid to safeguarding the storage of oil at points along the right of way, the loading and unloading of the oil, and the fueling of the tenders.

One of the obstacles to the determination of uniform standards lies in the wide variation in the flash test and viscosity test of the oils employed for fuel purposes in the different parts of the country.

A number of recommendations are made as to the design and location of large storage tanks and methods of fueling of tenders. (*Railway Age*, vol. 67, no. 22, Nov. 28, 1919, pp. 1069-1071, gp)

## REFRIGERATION

## Salt Precipitation from Mixed Solutions by Crystallization through Refrigeration

SALT PRECIPITATION BY REFRIGERATION, Berthold Block. In the chemical industry many salts have to be precipitated out of mixed solutions by means of crystallization. This is done by cooling the concentrated brines to the point where their ability to maintain the salts in solution is reduced.

Fig. 11 gives the solution curves of several salts in water, indicating how much of the salt at various temperatures may be contained in 100 grams of water (saturated solutions). As shown by these curves, the solubilities of various salts are unlike to an extraordinary degree and each salt will yield a greater or lesser precipitation out of a brine at a given temperature.

Thus, for example, in the case of Chilean saltpeter ( $\text{NaNO}_3$ ) cooled from 90 to 20 deg. cent. (194 to 68 deg. Fahr.), out of 165 grams held in solution at 90 deg. cent. so much is precipitated out that only 88 grams remain in solution.

The curves show that many brines can maintain quite considerable amounts of salt in solution even at 20 deg. cent. (68 deg. Fahr.) and that substantial amounts of crystals are precipitated only when the brine is cooled to a considerably lower temperature.

Because of this, provision has to be made for certain salts to cool the brine to quite a low temperature and Fig. 12, for example, shows an installation built to precipitate out of its solution potassium chloride. In this case 3000 grams of brine at 20 deg. when cooled to -10 deg. (14 deg. Fahr.) will precipitate out in crystal form 200 grams of potassium chloride.

The cooling is effected in two stages: by means of a water cooler to +20 deg. cent. (68 deg. Fahr.), and then in an ammonia refrigerating machine to -10 deg. cent. (14 deg. Fahr.).

The ammonia compressor *A* compresses the ammonia and forces it into a coil condenser *B*, in which ammonia under a pressure of 8 atmos. is liquefied by cooling water having a temperature of 15 deg. cent. (59 deg. Fahr.). The liquid ammonia, the flow of which is controlled by a special valve, is then again vaporized in the coils *C* of the crystallizing cooler *D*, the ammonia then going back to the compressor by means of pipe *E*.

The precipitation of the crystals is produced by cooling the brine in cooler *B*, the salt settling mainly on the cooling coils *C*. It is then swept off of them by special adjustable brushes, which also help to maintain the efficiency of the cooling action of the coil *C*. The crystals precipitated in this way sink through the brine and collect in the cone-shaped bottom of the cooler, whence they are from time to time discharged into the straining tank *O* through a quick-acting valve *G*. It is necessary to have the valve of a quick-acting type in order to have the liquid pressure discharge the crystals containing brine without letting out too much liquid itself. The straining tank *O* has on top a fine screen on which the brine falls. The thin liquid passes through and is strained off while the crystals remain on top of the screen and are collected therefrom from time to time.

In the installation described approximately 6000 calories (say, 24,000 B.t.u.) would have to be absorbed from the refrigerating plant per hour. In order to reduce the consumption of cold the installation is so arranged that the brine which leaves the crystallizing cooler *D* at *H* is conducted to the jacket of a second crystallizing cooler *J* and on the way precools the fresh brine which enters at *K* with the temperature of 20 deg. cent. (68 deg. Fahr.).

Brine entering with the temperature of -10 deg. cent. (14 deg. Fahr.) takes up heat to the extent of leaving the cooler *J* with the temperature of 5 deg. cent. (41 deg. Fahr.), whereas the fresh brine which enters with the temperature of 20 deg. cent. (68 deg. Fahr.) leaves with the temperature of 5 deg. cent. (41 deg. Fahr.). The salt which is crystallized out in the meantime is swept away by brushes in the same manner as in the first cooler and precipitates out through the quick-acting valve *L* into the same straining tank *O*. In this manner the consumption of cold is reduced to about one-half.

In computing the consumption of heat in refrigerating installations of this type it is necessary to bear in mind that in addition

to the heat which is necessary to cool the brine itself, quite considerable amounts of heat have to be taken care of as heat is given up in the process of precipitation by crystallization at the instant

FIG. 11 SOLUBILITY CURVES OF VARIOUS SALTS

when the dissolved salt passes into the form of crystals, the amount of heat thus given up being the same as that which was previously consumed in order to dissolve the salt. In the case of cooking salt about 20 calories per kilogram (35 B.t.u. per lb.)

FIG. 12 EMIL PASSBURG INSTALLATION FOR PRECIPITATION OF SALTS OUT OF SOLUTIONS BY REFRIGERATION

were consumed, for potassium chloride ( $\text{KClO}_3$ ) about 81.5 calories per kilogram (147 B.t.u. per lb.) and so on. (*Zeitschrift für die Gesamte Kälte-Industrie*, vol. 26, no. 8, August 1919, pp. 57-59, 3 figs., d)

## STEAM ENGINEERING (See also Railroad Engineering)

EMPLOYMENT OF NOZZLES INSTEAD OF CYLINDERS OR WHEELS IN TURBINES, Prof. R. Mollier. In 1904 Professor Dolder proposed in the *Schweizerische Bauzeitung* a new idea for the improvement of steam turbines, the main feature of which consisted in removing in the turbine only so much of the available energy of the steam jet that the steam might be able to regain its initial pressure in an expanded nozzle.

By these methods it was believed to be possible to shift the cycle at will into a range of high efficiency. The velocity in the turbine could be made as small as desirable and the compressor, which otherwise would be necessary with such a cycle, could be left out.

Professor Stodola denied the possibility of practically applying such a scheme. He pointed out the injurious effects of the resistances which would occur in all parts of the cycle, and brought forward as a deciding argument against the feasibility of such a cycle, the fact that the condensing steam always settles on the walls, which means loss of its kinetic energy.

The author states, however, that he himself was recently considering the same scheme in various forms; among others, its application in a reversed cycle to refrigerating machines, which he thought might be possible since with air or other non-condensable gases the fundamental objection brought forward by Stodola would not have to be considered. The scheme itself seemed to be highly attractive and if it could have been carried out in practice would have been of great benefit.

A closer investigation showed, however, that the presence of excessive resistance, which was only barely indicated by Stodola, offered an insuperable objection to the carrying out of this scheme.

It is the custom to carry out all kinds of changes of state of gases, in particular cyclic changes, in one or more cylinders with movable pistons and predetermined addition or abstraction of heat. There is, however, another way to do it and that is by substituting for the cylinder with movable piston a duct with variable cross-section through which the flow of gas takes place. If we neglect the question of frictional resistance the addition and absorption of heat will be the same as in the case of a cylinder with a movable piston.

In a cycle of the character occurring in the case of a duct of variable cross-section, there will be instead of work directed on to the piston a variation of kinetic energy of the gas. Should the cycle be continuous, we would then have to construct a circular duct, and the excess of energy created by the process would have to be abstracted from the gas at some point of the cycle, for example, by means of a turbine; or, if the cycle is of such a character that the kinetic energy of the gases is reduced, then at some place in the cycle this loss of energy would have to be made good by some means, for example, by a turbo-compressor. In both processes, however, the rule holds good that on the whole the amount of work either gained or expended by the gas is equal to the amount of heat that is either abstracted from or delivered to the same gas.

In cycles of the first class, that is, cylinders with movable pistons, the velocities of the gas are so small that the work necessary to overcome the resistance thus produced may be neglected entirely, and in a cycle of this character the integrals

$$\int p dv = - \int v dp \quad \text{and} \quad \int T ds = - \int s dT$$

may be taken as fully representing the work gained during the cycle or the work expended to carry it out. In these equations  $p$ ,  $v$ ,  $T$  and  $s$  represent respectively the pressure, volume, absolute temperature and entropy of the gases.

In the cycle of the second class, that is, a duct with variable cross-section, the resistance cannot be neglected since in that case we are dealing with great, and often very great, velocities.

In a cycle of that character the work gained or lost cannot be expressed by the above integrals and the area of the cycle cannot be expressed in the  $p$ - $v$  or  $T$ - $s$  diagrams. As a matter of fact it is greater or less than that expressed by the above integrals, by

the amount of the work of resistance  $W$ , so that the variation of energy is in that case expressed by

$$E = - \int v dp - W$$

Because of this, it appears that if in a heat engine the friction is equal to the integral of the area of work, the whole work produced by the engine disappears and the engine fails to work. The amount of heat introduced from outside is entirely consumed but at the same time a certain amount of heat passes from the hot body (working chamber of the engine) to the cold body (cooling jacket, however expressed).

The author considers in detail the amounts of resistances which are met with in the cycle proposed by Professor Dolder, whether it be for the case of a steam turbine or an air refrigerating machine, and shows that the resistances are so great as to make the ultimate efficiency of the cycle extremely low. (Ueber die Anwendung von Düsen an Stelle von Zylindern oder Kreisrädern, *Zeitschrift des Vereines deutscher Ingenieure*, vol. 63, no. 35, August 30, 1919, pp. 830-833, 6 figs., t)

DEFLECTION OF STAYBOLTS IN LOCOMOTIVE BOILERS, Geo. L. Fowler, Mem.Am.Soc.M.E. As the length of fireboxes increased there was an increase in staybolt breakages and while there were many theories as to the cause of it, the amount of experimental data was quite limited.

In the present investigation an attempt was made to determine by actual measurement the amount of relative movement between the inner and the outer sheets of a locomotive firebox and also when the motion occurred and what was its general character.

The apparatus used was designed to resolve the motion of the inner sheet relatively to the outer one into its vertical and horizontal components and project them on a screen. These were afterward recombined to plot this relative movement in the form of a diagram.

The investigation is so extensive that only some of its conclusions can be reported here. The fundamental facts brought out were that the staybolt deflection is much greater in a flexibly stayed boiler than in a rigidly stayed boiler. It appears also that during the whole period of operation and probably until the boiler temperature has reached that of the atmosphere, the staybolt is in constant motion. The two types of boiler construction (Wooten and radially stayed) have quite different effects on staybolt deflection and firebox temperatures, and the action of the tubes has a marked influence on staybolt deflection at the front end of the firebox.

The tests also showed the great sensitiveness of the plates to changes of temperature. For example, a cold boiler may be filled with water of any temperature from cold to boiling and there will be no relative motion between the sheets. But let the fire be laid and a piece of lighted waste thrown in to ignite it, and it has, thus far, been impossible to get a reading before the sheets would show a movement, though this has been done within 10 s. e. from the time of ignition of the waste.

The general impression left by the tests is that the Wooten firebox is much more rigid than the wide firebox when rigidly stayed with radial stays, and the difference might be still greater if it were given a complete installation of flexible bolts.

Because of the great sensitiveness of the sheets to changes of firebox temperature, it would appear that a boiler which is so built as to permit the sheets to expand under the influence of temperature changes will put less stress upon the staybolts and sheets than one where such motion does not exist.

The tests apparently left the observers with the conviction that the flexible bolt has superior possibilities as a means of reducing the probable stresses that the several parts of the boiler are called upon to sustain. (*Railway Age*, vol. 67, no. 23, December 5, 1919, pp. 1088-1094, 13 figs., cA)

## TESTING AND MEASUREMENTS

TESTING ABRASIVE WHEELS FOR EFFICIENCY, Raymond Francis Yates. Description of methods for testing abrasive wheels and some of the results obtained.

There are cases where it is necessary to determine the efficiency of various types and makes of abrasive wheels. In particular, the manufacturer of such wheels must have methods to determine which of his products gives the best efficiency.

Wheels are made in various grits, grades and bonds. By grit is meant the size of the abrasive particles that constitute the wheel, the particles being graded by the number of meshes to the square inch on a screen through which they pass. Thus, 10 would represent a very coarse wheel, while 200 would indicate a wheel composed of fine particles. Grade indicates the nature of the abrasive substance as regards its temper or hardness, and electrothermally it is now possible to produce abrasive substances of desired hardness. The bond of a wheel is the substance that holds the abrasive particles together in a solid form. It is extremely important and is a large factor in the determination of the efficiency of the wheel when cutting certain substances. For instance, if a wheel is cutting cast iron and its bond is not of the proper nature the particles may lose their sharpness and yet remain in place, or the bond may not be able to hold until they become sufficiently dull to break away from the rest of the wheel. In the first place very low cutting efficiency will result, as the dull abrasive particles hang on to the wheel and cause undue friction in rubbing over the surface of the iron. In the second case the wheel may cut freely and quickly, but will wear down very rapidly. (*American Machinist*, vol. 52, no. 3, Jan. 15, 1920, pp. 139-141, 6 figs., *ep*)

## THERMODYNAMICS

SPECIFIC HEAT OF AIR AT ROOM TEMPERATURE AND AT LOW TEMPERATURES, Karl Scheel and Wilhelm Heuse. An extensive paper of which only the conclusions can be given here on account of limited space available.

The specific heats of air were determined by means of two calorimeters and the average data of observations are presented in Table 2, where, in addition to the direct readings, are given the corresponding units in calorie masses obtained from electric mass by multiplying the latter with the heat equivalent of the watt-second, which is

$$0.23865 \frac{\text{g-cal.}}{\text{watt-sec.}}$$

The tests confirm what has already been found by Swann, namely, that the specific heat of air at room temperature is considerably greater than that found by previous investigators, in particular by Regnault.

The value given by Swann in calorie mass units, namely,

$$0.24173 \frac{\text{g-cal.}}{\text{g-deg.}}$$

was based on the value of 20-deg. calorie = 4.186 watt-seconds. From this may be computed the comparable value of the specific heat of air at 20 deg. in electric mass units

$$1.010 \frac{\text{watt-sec.}}{\text{g-deg.}}$$

which agrees perfectly with the results obtained by the present writers.

The value of the specific heat permits us also to determine the relation between the specific heats of air in accordance with the formula  $c_p/c_v = \gamma$ . Usually

$$c_p - c_v = T \left( \frac{dp}{dT} \right)_s \cdot \left( \frac{dv}{dT} \right)_p$$

If one wishes to determine the values on the right-hand side of the equation, the van der Waals equation of state, then for atmospheric pressure and room temperature one obtains

$$c_p - c_v = \frac{R}{M} \times 1.0045 \frac{\text{watt-sec.}}{\text{g-deg.}}$$

where  $R = 8.316$ , which is the gas constant, and  $M = 28.95$ , which is the molecular weight of air. Hence

$$c_p = 1.009 \frac{\text{watt-sec.}}{\text{g-deg.}}$$

$$\gamma = 1.400$$

When the temperature decreases, the specific heat of air increases. The increase is noticeable at  $-78$  deg. cent. and reaches the value of about 5 per cent at  $-183$  deg. cent. When the pressure is reduced to  $\frac{2}{3}$  atmosphere, the increase of specific heat is still noticeable at  $-183$  deg. cent., but has a smaller numerical value (3 per cent). It appears, therefore, that qualitatively in the neighborhood of its point of condensation, air shows the same behavior that Knoblauch and Jakob, and later Knoblauch and Mollier, have found for steam.

According to Linde the specific heat  $c_p$  at pressure  $p$  and absolute temperature  $T$  may be represented by the specific heat  $c$  of the ideal gas state independent of the temperature, that is, for the case of infinitely small pressure, when the following equation holds good:

$$\frac{c_p}{c} = \left( 1 - \frac{ap}{T^2} \right)^{-\frac{2}{\gamma}}$$

The constant may be calculated from experimental observations of the Joule-Thomson effect. If  $p$  is measured in atmospheres, then for air  $a = 21,500$ . According to the tests of Linde this relation holds good for the case of small pressures down to the temperature of condensation of air.

With the aid of this formula it is possible to eliminate  $c$  and to determine from the specific heat  $c_p = 1.009$  at room temperature and atmospheric pressure the specific heat  $c_p$  at equal or different pressure and at a lower temperature. One finds that under atmospheric pressure at  $-78$  deg. cent.  $c_p = 1.013$  and from this value and the Linde equation the specific heat at  $-183$  deg. cent. is  $c_p = 1.065$ , while at a pressure of  $\frac{2}{3}$  atmosphere and  $-183$  deg. cent.  $c_p = 1.045$ , all values being in watt-seconds per g-deg. Within small fractions of one per cent these figures equal with the values found experimentally. (*Zeitschrift für Sauerstoff- und Stickstoff-Industrie*, vol. 11, nos. 9-10, May 1919, pp. *d*)

TABLE 2

Temperatur, deg. cent.	Specific Heat $c_p$	
	in watt-seconds g-deg.	in calories g-deg.

## VARIA

OIL VERSUS COAL FOR USE ON SHIPBOARD. The following statement in *Power* at the end of an article describing stokers for use on shipboard is highly significant.

The navies of the world will use oil regardless of price. So, too, will fast passenger ships. It is believed by many that there is not enough oil to warrant its wide use in the merchant marine for many years, although within recent weeks rich oil finds are reported from Colombia. Just now American coal is selling in Italy for \$36 a ton. The freight rate is \$22. So it is not bad business now to use oil-burning ships in the coal trade to Europe. Yes, the mechanical stoker for ships is here, and when oil again becomes high-priced or its supply alarmingly diminished, it will come into its own. (*Power*, vol. 51, no. 3, Jan. 20, 1920, pp. 86-89, 8 figs., *g*)

## CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

## CORRESPONDENCE

**C**ONTRIBUTIONS to the Correspondence Departments of **MECHANICAL ENGINEERING** by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

### Screwed Pipe Joints

TO THE EDITOR:

Very little attention is paid to the manner in which screwed pipe-thread joints are made. It is generally up to the pipe fitter to put red lead or some other kind of dope on the threads and then exert all his strength to screw the pipes together. When he comes to test the joints, however, he finds a goodly percentage of

FIG. 1

FIG. 2

FIG. 3

them leaky. As a last resort he will apply a peening tool to close up the leaks, a thing that should not be done, as in most cases it only stops them for a short time. But the fault is not his, it is mostly the fault of the pipes and fittings—the way they are threaded.

In the first place, all pipe threads are supposed to be made to the Briggs Standard gage. It is almost impossible for the manufacturers to do this, as a tool made perfect to the Briggs Standard will not stay that way very long in practical work. It is most natural that the sharp point of the thread on the tap or die will

wear first, as shown by the male part of Fig. 1, and, as it would be utterly impractical to discard a tap or die before the shape varied from the Briggs Standard shape by a reasonable amount of wear, there ought to be some allowance made first in the making of the tool and then in the working gage. For instance, a perfect female pipe and male pipe that have been threaded with tools that have cut a good many threads before, as in Fig. 1, will never make a good joint except by applying main force, which should not be done. If, however, the bottom of the female thread were flattened somewhat, as shown in Fig. 3, the pipes would screw together with very little force; the sharp points on the male and female threads would be of such shape that they would float in place, the sides of the threads would come together and a good joint would result throughout, as shown in Fig. 2.

It is an easy matter to keep the tool so it will make a thread as shown in Fig. 4 for the male pipe, and in Fig. 5 for the female. The width of the flat part of the thread could vary from  $1/10$  to  $1/8$  of the depth of the sharp V-thread, and a joint would always

FIG. 4

FIG. 5

be made by floating the sharp point of the thread against it. As a matter of fact, however, the flat of the thread will be a round fillet, the sharp point of a tool will soon wear round, and if made flat it will still wear round after it has performed a small amount of work.

Manufacturers have been reluctant to admit that the threads on fittings and pipes are not perfect to Briggs Standard, and it is high time to overcome that difficulty by making the working gage so it will gage the sides of the threads and not ride at the bottom when the thread is not perfect. I have seen pipes and fittings gaged with a Briggs Standard gage that were apparently all right, but when screwed together they would not make a joint for the simple reason that the female thread would be too large and the male thread too small. The crests of both the male and female work gages should be flattened to an extent not less than the U. S. Standard thread flat or one-eighth the depth of sharp V-threads; in fact, if one-sixth were taken off it would be still better.

## Discussion of the Horsepower of Resistance

TO THE EDITOR:

A measure of performance of tractive machines which is convenient for broad generalizations is

$$\frac{\text{weight} \times \text{speed}}{\text{horsepower}} \quad \text{or} \quad \frac{WV}{H}$$

For the battleship *Pennsylvania*, this coefficient has the value 47,000, based on shaft horsepower. A freight train with a resistance of 10 lb. per ton at 20 miles per hr. gives a coefficient of 75,000. In general, the value of the coefficient is  $C = 750,000 \div Rt$ , where  $Rt$  = resistance in lb. per ton of weight.

A man on a bicycle may realize a value of  $C$  around 40,000. For an average pleasure automobile,  $C = 5000$ . The lowest values of all are realized with airplanes, because these machines sustain as well as propel. The NC transatlantic hydroplanes give  $C = 1900$  at 80 m.p.h. The usual range is from 1400 to 1800. High speeds always tend to reduce  $C$ , because power increases faster than speed.

Since for an airplane  $H = dI^3(KDA + Kp) \div 375$ , the coefficient becomes

$$C = \frac{375W}{dV^2(KDA + Kp)} = \frac{375W}{R} = \frac{375}{\tan \theta}$$

where  $R$  = total resistance, lb., and  $\theta$  is the gliding angle. The coefficient in question is therefore (in homologous units) simply the reciprocal of the gliding angle. It should have a high value, as the gliding angle should have a low value. Since  $Rt = 2000$   $R \div W$ ,  $C = 750,000 \div Rt$ , as above.

Efficient airplane flight seems, therefore, to involve high altitude (low  $d$ ), a proper wing form, and low parasite resistance. The question of altitude is influenced, however, by the falling off of engine power at high altitudes.

## Economic Loss Caused by Rust

TO THE EDITOR:

The actual economic loss and wastage of steel and iron tools, machines, vehicles, agricultural machinery and implements, parts and supplies of all kinds, due to rust from moisture condensation and to corrosion from fumes, etc., must be enormous.

Are any data or statistics available which express this loss?

INDUSTRIALIST.

New York City.

## WORK OF THE BOILER CODE COMMITTEE

*THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.*

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 262-266, inclusive, as formulated at the meeting of December 2, 1919, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

### CASE NO. 262

*Inquiry:* Does the term "equivalent pitch for cylindrical surface" as referred to in Par. 212c of the Boiler Code apply to the outside shell or to the inside shell?

*Reply:* It is the opinion of the Committee that this term in the formula of Par. 212c refers to the surface to be stayed, which in this case is the inside shell.

### CASE NO. 263

*Inquiry:* *a*—Is it the intention that Table 5 of the Boiler Code which specifies the maximum allowable stresses for stays and stay-bolts shall apply to iron as well as steel stays? Are sub-items *a*, *c* and *e* supposed to apply to iron as well as to steel?

*b*—Is it assumed by the Boiler Code Committee that an ordinary expanded boiler tube has no holding power in the tube shell whatever? What holding power is a beaded tube or a welded tube supposed to have?

*Reply:* *a*—Items *a* and *c* of Table 5 apply to iron as well as steel, but in accordance with the requirement of Par. 4, item *e* applies only to iron.

*b*—It is the opinion of the Committee that tubes which are merely expanded in the tube sheets have a large initial holding power. However, under practical conditions of operation, where the seating of the tube in the sheet is disturbed, the holding power of tubes so attached is different. It was for this reason that the Code requires either beading, flaring or welding in of tubes. There have been many tests made on the holding power of tubes, the results of which may be found in technical literature and handbooks.

### CASE NO. 264

*Inquiry:* What form of test will be required for the shell of a miniature boiler formed by the cupping and hot-drawing process from a sheet of firebox plate which meets the requirements of the Boiler Code? It is believed that the specifying of firebox boiler plate steel and subjecting each finished cupped and hot-drawn shell to an hydrostatic test, using the formula  $P = 32,000/t/D$ , and the flattening test of a coupon cut from each cupped and drawn piece, this flattening test to go to 5 times the wall thickness, would be sufficient guarantee of the finished material and would be far more representative and better test than taking tests from the material before the cupping and hot-drawing operations.

*Reply:* It is the opinion of the Committee that if the firebox plate material from which the boiler shell is formed meets the requirements of the Boiler Plate Specifications of the Code, and if the shell is properly annealed after drawing, it may be considered as having met the requirements of the rules in the Boiler Code. The Boiler Code Committee has been informed that for proper annealing, the shell should be subjected to a temperature of 1550 deg. Fahr.

### CASE NO. 265

*Inquiry:* Is it the intent of Par. 25 of the Boiler Code that chemical limits for carbon are applicable only to firebox plate and not to flange plate?

*Reply:* The Specification for Boiler Plate Steel in the Code, which is in conformity with the similar specification of the American Society for Testing Materials does not specify any chemical limits for carbon in steel plate of the flange grade.

### CASE NO. 266

*Inquiry:* Does not the reply given in Case No. 206 conflict with the rules in the Boiler Code for calculation of structural

members for the stiffening of unstayed portions on heads of boilers?

Reply: It was not the intent of the Boiler Code Committee in Case No. 206 to indicate that the stiffening effect of the members used to attach the braces to the head could be added to the value of the braces, in determining the maximum allowable working pressure for which the design was constructed.

## SPECIALIZED CURRICULA IN ENGINEERING COLLEGES<sup>1</sup>

By A. A. POTTER, MANHATTAN, KAN.<sup>2</sup>

THOSE who are responsible for the conduct of engineering departments at universities or colleges are urged by some to develop specialists, and by others to make the curricula broad. Some alumni, particularly during their first few years after graduation, advocate courses to meet the needs of the special industries, others feel that engineering schools are now devoting too little time to basic principles and facts.

Mr. Benjamin G. Lamme, chief engineer of the Westinghouse Electric and Manufacturing Company, in discussing technical training for engineers before the Pittsburgh Section of the American Institute of Electrical Engineers in 1916, made the following remarks concerning specialization:

There has been quite a fad for specialization in engineering training. The writer's personal opinion is that specialization in college training is not advisable, except possibly in a very general way. There has been a false idea in many schools that if a man specialized along some individual line of work it would advance him more rapidly when he leaves school for active work. The writer almost never asks the student in what field he specialized.

In college training the time spent on commercially practical details is usually largely wasted, as it may give the student entirely wrong ideas. The colleges should aim to develop analytical ability, imaginative faculty, ability to do independent thinking. . . . A broad general training is most desirable for the man who has ability to do something in the world.

The majority of engineering colleges are devoting their chief attention to curricula in civil engineering, electrical engineering and mechanical engineering. There seems also to be considerable demand for men trained in mining engineering, chemical engineering, architecture and architectural engineering. Several institutions are also offering curricula leading to degrees in agricultural engineering, ceramic engineering, flour-mill engineering, highway engineering, railway engineering and industrial engineering. Specialized curricula have also been proposed in business engineering, petroleum engineering, aeronautical engineering, etc.

An investigation has been made of the ground covered at twenty-four representative institutions in their civil, electrical and mechanical engineering curricula with results as follows:

About fifteen per cent of the total time is devoted to mathematics, twelve per cent to physics and chemistry, eight per cent to English and other modern languages, ten per cent to mechanics and hydraulics, three per cent to economics and business organization, five per cent to elementary engineering drawing, about thirty per cent to specialized engineering subjects, and about fifteen per cent to related engineering subjects.

The specialized subjects in a civil-engineering curriculum usually include: surveying, masonry and foundations, bridge design, railways, highways, drainage irrigation, water supply, sewage disposal, and concrete construction. The related engineering subjects include shop practice, elements of power engineering, and elements of electrical engineering.

In the electrical-engineering curriculum the specialized subjects usually include: theoretical electricity, direct- and alternating-current machinery, electrical measuring instruments, power engineering, telephony, electric railways, and electric design. The related engineering courses are usually thermodynamics, shop practice, machine design, surveying and factory organization.

In the mechanical-engineering curriculum the specialized subjects include: machine design, shop practice, thermodynamics, power engineering, power-plant design, heating and ventilation, refrigeration and factory organization. The related subjects are electrical machinery, structural design, and surveying.

An analysis of the various specialized curricula will reveal the fact that they differ mainly by name from those in civil, electrical or mechanical engineering. Such specialized curricula are usually chosen by the adventurous and poorer students who are attracted by good-sounding names.

Employers of graduates from engineering schools are usually not concerned with the name of degree the young engineer holds. The large electrical manufacturers do not differentiate between those trained as electrical and those trained as mechanical engineers. A representative of a telephone company stated that his company is willing to accept men trained in any engineering course, but that he does not care to select men from schools who claim to train telephone engineers.

If it were possible to predict the line of work the student will enter after graduation, certain specialization might be justified. Even in such cases a broad engineering training would be preferable, as the young engineer will find that his work will necessarily specialize him and will so absorb his energies as to leave him very little time to acquaint himself with related specialties. Records of graduates from engineering schools show that, while the majority follow some branch of engineering, comparatively few remain in the particular field which they had expected to enter when at college.

Dean M. E. Cooley, President of The American Society of Mechanical Engineers, in the September 23, 1919, issue of the *Engineering News-Record* makes the following statement:

Engineers are not wholly blameless for the position in which they find themselves—a responsibility which the engineering colleges must share. They have devoted altogether too much time to professional subjects. In their zeal to fit themselves for work in the field of their choice, non-technical subjects which make for breadth have been sacrificed. Thus they are narrow, are fenced in so that neither can they look out nor can others look in.

Close observation of the records of hundreds of graduates from engineering schools leads the author of this paper to the opinion that better results would be accomplished if the majority of engineering colleges would devote their energies to two curricula, one dealing mainly, in its applications, with static engineering and the other with dynamic engineering. In the first curriculum should be included the courses now in the civil-engineering curricula of our best schools and should familiarize the student with the broad principles underlying the design and construction of railways, highways, irrigation and drainage projects, masonry, concrete, sanitation, and business administration. In the dynamic-engineering curriculum should be included the fundamental courses now given in the electrical- and mechanical-engineering curricula, with considerable emphasis on factory management, power engineering and business administration.

Curricula in mining engineering, chemical engineering and architecture should be offered only by a small number of institutions. There may also be need for a few colleges to offer graduate courses or short courses which will prepare men for certain specialized work in the industries. Admission to such courses should be limited to men who have had considerable practical experience.

Experience indicates that broad engineering education will enable the college graduate to reach greater usefulness in his profession than will specialized technical training.

According to Albert Reeves, General Manager of the National Automobile Chamber of Commerce, 1,892,000 motor vehicles were built in the United States in 1919, of which 305,000 were motor trucks. Two hundred and sixty manufacturers were engaged in this production, employing 580,000 workmen. The wholesale value of these vehicles was, in round figures, \$1,808,000,000. There are approximately 7,100,000 motor vehicles registered in the United States, of which 700,000 are motor trucks, these latter having displaced, it is estimated, over 3,500,000 horses.

## Mechanical Engineers to Meet Next May at St. Louis

The Spring Meeting of The American Society of Mechanical Engineers is to be held at St. Louis, May 24 to 27, the first meeting being on Monday of the week of the convention in accordance with the plan followed so successfully at Detroit last year.

In view of the interest throughout the Mississippi Valley and in the territory contributory to it, one session will be devoted to a discussion of river-transportation problems, and the movement now under way for the development of transportation on the Mississippi River, with New Orleans as the port for shipment of goods to South American and other countries. Another session will be devoted to the subject of the Valuation and Appraisal of Industrial Properties, using as material the papers presented at the last Annual Meeting, upon which discussion is being solicited by the Committee on Meetings and Program. Papers are also in prospect on fuels, oil engines, measurement of the flow of water, transmission of heat, pumping engine tests, aeroplane design, etc. A paper is to be presented by the recently elected Honorary Member of the Society, A. C. E. Rateau, of France, on Turbo-Compressors for Increasing the Power of Aeroplanes at High Altitudes. It is also expected that papers will be presented by the Mid-Continent Section, representing the oil districts of Oklahoma, on subjects relating to the distribution and use of oil for industrial purposes.

St. Louis is a rapidly growing industrial center, with one of the most progressive Chambers of Commerce in the United States, engaged in educational work for the increase of production in agriculture and industry, both locally and throughout the state, and for the improvement of industrial conditions. A large housing undertaking is under way upon which there will be a contribution at the meeting. An immense plant being erected by the Chevrolet Motor Company is one of the influential factors in bringing about this movement. There are numerous manufacturing plants, some of large size and several of the most modern equipment, undertaking unusual lines of work of interest to members of the Society.

The parks of the city, with the outdoor municipal theater and the Art Museum in a location remarkable for its beauty and extent of view, are among the finest in the country. The hotel accommodations are good and modern, and altogether the city is an ideal place for a meeting of engineers, and a whole-hearted welcome is assured on the part of the local members and their many friends of the city, both within and without the profession. St. Louis is proud of her accomplishments industrially and as a civic community, and justly so. The Committee on Meetings and Program and the officers of The American Society of Mechanical Engineers are gratified at the opportunity which the city has extended to the membership for a convention which promises to be one of the greatest in the history of the Society.

## What Is Engineering?

The Committee on Development of the American Society of Civil Engineers, in its report to the Board of Directors presented on October 14, submitted the following definitions of engineering:

1 Engineering is the science and art of directing the great sources of power in Nature to the use and convenience of man.

2 Engineering is an art and a science. It is a science in so far as physical laws are its base, and an art in so far as in the application of these laws the things designed and constructed develop the spirit of progress, the creation of wealth, and the well-being of all peoples.

Engineering is generally divided into four major divisions, viz., civil, mechanical, electrical, and mining.

The practice of engineering requires knowledge of physical laws, forces, and the materials of Nature.

The professional engineer is one who by reason of special training, education, and experience is qualified to design and direct the construction of engineering work in one or more of the major divisions of engineering.

3 Engineering is the creative science and art of applying economically the materials and forces of Nature to the use and convenience of man.

4 Engineering is the science of industrial effort, and the science and art of applying this effort for the welfare of the public.

An engineer is one versed in the science and art of industrial effort made for the purpose of public welfare.

## Civilization Follows Transportation

Many years ago Professor Metchnikoff, of the Pasteur Institute, Paris, better known for his work in the field of biology and micro-pathology, published a book dealing with the history of ancient civilization.

He showed that civilization followed the course of the great rivers, which was only natural in the light of our modern knowledge. Great cities as well as even such crude manufacture as existed in the ancient world required the movement of goods, such as food and building and raw materials, and in a roadless world the rivers presented the only available cheap means of communication.

In this country the early settlements followed the same water paths. The Hudson and Ohio rivers, and later on the Mississippi, were the great liquid roads carrying the early American commerce and settlers.

As civilization moved, however, and the wealth of nations increased, the rivers were not sufficient to carry on the commerce of the world and canals were dug, at first as outlets for rivers into more convenient directions or as connecting links between important rivers, and later on as more or less independent means of communication. This represents the basic transportation tendency of the 18th century and the early days of the 19th century. The historical Manchester Canal in England is one of the best illustrations of this phase of the transportation problem in Europe, and the Erie Canal, which practically made an empire state of New York, serves as a good example of the application of

this same principle to conditions throughout the entire United States.

But water transportation is at best only a makeshift. It is slow and, when created artificially, by no means cheap. In North America it is closed to users for several months in the year. Further, water carriers have to be large in order to be economical, which in turn means that the goods shipped have to be either in bulk character or have to be accumulated until there is enough to fill a steamboat. All this corresponds to the stage of economic development when industry was still moving slowly.

The next stage was the creation of the railroads, which have been the means of opening immense regions of the country devoid of rivers or canals. The great American Northwest, the mining regions of the central Rockies, and the wealthy states of the Pacific slope could not have been opened to settlement or commerce without the railroads.

In the 75 years of the railroads' existence, however, it has been found that they also have certain limitations. While they represent the most economical means of transportation over distances in excess of, say, 200 miles and for shipments not below a certain relatively moderate bulk, an insistent demand arose for an economical means of transportation of goods below the transportation range of the railroads, especially for distances less than 100 miles, or what might be called urban-circle deliveries. When a legitimate demand on a large enough scale arises, it is usually promptly satisfied, and the motor truck came to the relief of those who needed that type of transportation.

One more transportation question has been looming up for the last 25 years at least, and that is transportation between widely scattered localities where there are neither roads nor rivers, and where the comparatively small volume of traffic does not justify the construction of railroads. In the sparsely populated mining regions of South America, in the outlying settlements of Africa, in the islands of the Pacific, there was a demand for a way of rapidly conveying passengers and comparatively small amounts of goods and for exporting the products of local industries, such as rubber, gold, and other minerals. This problem cannot yet be considered to be definitely solved, but a promise of its solution lies in the recent rapid progress of the aeroplane and dirigible. The whole history of the improvement of the means of conveyance shows, however, that as means of transportation have improved civilization has followed in its way. As the rivers helped to build up ancient cities and the earlier towns of the Western Hemisphere, so the Erie Canal has helped to build the Empire State, the railroads have opened Minnesota, the Dakotas and Manitoba, the motor trucks are now opening up the farming communities throughout the country, and the aeroplanes will make possible the development of the rich mines of Central and South America and South Africa; and in the far distance loom still greater possibilities of which it would now perhaps be premature and but a flight of fancy to discuss.

### The "Mysterious Mr. Smith"

The story of how the new buildings and some of the equipment of the Massachusetts Institute of Technology in its new site on the Charles River Basin, Cambridge, Mass., were made possible by the munificent contributions of a certain "Mr. Smith" is generally known by all who have kept in touch with technical education in this country.

Who this Mr. Smith was, however, has been a zealously guarded secret, until at a recent jubilee dinner of the alumni of the Institute, to celebrate the successful completion of a drive for a \$4,000,000 endowment, the real name of this benefactor of the M. I. T. was disclosed as Mr. George Eastman, the "Kodak King" of Rochester, N. Y.

In 1914 the Massachusetts Institute of Technology celebrated the fiftieth anniversary of its chartering and marked the occasion by deciding to move from its outgrown buildings which had become a landmark in the Back Bay district of Boston, to its present location in Cambridge. Later, President Maclaurin of the Institute, himself a physicist of renown, spent a day at the works of the Eastman Kodak Company, where he was greatly impressed

by the high order of scientific attainment in the laboratories and manufacturing departments of this great plant. Mr. Eastman was not at Rochester at the time and Dr. Maclaurin therefore wrote him asking for a conference with regard to the problems and opportunities of the Institute and its possibilities for the development of scientific work. They met at dinner in New York, and Mr. Eastman was so interested in the project for rebuilding Technology that he at once gave \$2,500,000, expressing the desire that a comprehensive plan for the new buildings should be followed and the usual incoherent, piecemeal construction for such institutions avoided.

As the work progressed, \$1,000,000 more was added, and just before the dedication of the new monolithic structure in which the Institute is now housed, he offered five dollars for every three that others contributed up to a limit of \$2,500,000, an offer which was fulfilled. Still other donations were subsequently made and finally, when the drive for the \$4,000,000 endowment above referred to was completed, Mr. Eastman matched it with a sum of equal amount. His total gifts to the Institute have amounted to \$11,000,000, all of which, with the exception of a quarter of a million specifically for chemical engineering equipment was given anonymously.

Mr. Eastman preferred to keep the real name of the donor a secret in order to avoid notoriety and only disclosed it because of the legal requirements incident to the transfer of stock made necessary at the time of his latest gift of \$4,000,000. Naturally there has been a great deal of guessing as to who was "Mr. Smith." Among those suspected were Frick, Rockefeller, Vail and DuPont, the latter a Technology alumnus who has contributed large sums to his Alma Mater under his own name. There also were many amusing incidents in this connection, of people who had announced definitely that they, or some one of their friends, were the man; and of wealthy suspects who met and accused each other of keeping under cover, and who separated believing that the other fellow was a colossal bluffer.

The authentic announcement of Mr. Eastman places him as one of the greatest supporters of technical education in America, and it is a pleasure to know that the gifts have come from one who, through his own experience, has full appreciation of the value of such education.

### Conference on National Safety Codes

A general conference on safety codes was called by the Bureau of Standards at Washington, for December 8. This conference was attended by representatives of a very large number of organizations interested in the preparation of standard safety codes, including engineering societies, trade organizations representing all phases of industry and City and State commissions. By a vote taken at this conference, the American Engineering Standards Committee was asked to request the National Safety Council, the International Association of Industrial Accident Boards and Commissions, and the Bureau of Standards acting together to appoint an Advisory Committee of fifteen for three purposes, viz.,

- (1) to determine the order of priority in the development of safety codes
- (2) to recommend to the A. E. S. C. suitable sponsor and joint sponsor bodies
- (3) to make report, after preliminary study, not later than February 1.

This matter was taken up by the American Engineering Standards Committee at its meeting on January 3 and the Committee took favorable action on the recommendation of the Conference. A committee of fifteen was immediately organized and held a meeting in Washington on January 9, at which the following members were present:

- F. D. Patterson, representing Pennsylvania Department of Labor and Industry.
- W. C. L. Eglin, representing National Electric Light Association, Committee on Safety Rules and Accident Prevention.
- M. G. Lloyd, representing Bureau of Standards, Safety Section.

Royal Meeker, representing U. S. Bureau of Labor Statistics.  
L. W. Chaney, representing U. S. Bureau of Labor Statistics.  
Dana Pierce, representing Underwriters' Laboratories.  
W. P. Eales, representing The American Society of Mechanical Engineers.

E. B. Rosa, representing Bureau of Standards.

A. W. Whitney, representing National Workmen's Compensation Service Bureau.

S. J. Williams, representing National Safety Council.

P. G. Agnew, Secretary, American Engineering Standards Committee was also present.

The Committee first organized itself with Dr. E. B. Rosa as Chairman and Dr. Royal Meeker as Secretary. It then adopted the name of "National Safety Code Committee."

A total of 63 Safety Codes on as many subjects were scheduled by Dr. Rosa for consideration. Those for which The American Society of Mechanical Engineers was suggested as sponsor, are as follows:

- Elevators and Escalators
- Stationary Steam Boilers
- Non-fired Pressure Vessels
- Boiler Room Equipment and Operation
- Steam Engines and Turbines
- Internal Combustion Engines
- Engine-Room Equipment and Operation.
- Ladders
- Locomotives

A number of other codes were discussed, some of which in all probability will be assigned to this Society, but no definite decision on these was reached at the time of this meeting of the Joint Advisory Committee.

## Technical Papers at Annual Meeting of Society of Automotive Engineers

A number of interesting professional papers were presented at the annual meeting of the Society of Automotive Engineers, held in New York, January 6 to 8. In a paper on Preignition of Spark Plugs, Stanwood W. Sparrow of the U. S. Bureau of Standards, described tests on specially prepared spark plugs, which indicate that one of the main causes of preignition is the lack of proper cooling of a spark-plug element, and in some cases improper design of the engine itself. The lack of proper cooling of the spark-plug elements may be due either to improper design of the plug or to subsequent causes preventing its proper preparation.

Major George E. A. Hallett, chief of Power-Plant Section, Engineering Division, Air Service, Dayton, Ohio, presented general data on the use of superchargers for aircraft engines. The conclusion to which the author comes is that supercharging in principle is of value to several classes of military aeroplanes, as well as to certain types of civilian planes. As a graphic illustration of the advantage of supercharging, it was pointed out that at 25,000 ft. altitude a supercharged 250-hp. engine will deliver as much power as a 1000-hp. engine without supercharging apparatus.

Interesting considerations on Dilution of Engine Lubricants by Fuel in Automotive Engines were presented by Gustave A. Kramer, of the U. S. Bureau of Standards. Among other things were described experiments to determine the effect of dilution by fuels on the viscosities of lubricants, the fuels being diluted either by an average grade of fuel gasoline or by commercial kerosene. The author suggested the use of an oil renovator as part of the engine itself.

The important problem of the use of low-grade fuels in the automotive engines was discussed briefly by J. G. Vincent, vice-president in charge of engineering, Packard Motor Car Company, Detroit, Mich., who suggested among other things, the use of a special manifold for preheating fuel with an automatic method of regulating the heat. The principle of the device is the employment of a difference in pressure existing on either side

of the carburetor butterfly valve; a small amount of the combustible mixture is caused to pass through a passage which is in parallel with the main carburetor passage whereupon the mixture is burned in a suitable burner and the burned gases are allowed to mix with the incoming main supply to the engine above the throttle.

Notwithstanding the great progress made in the application of the constant-volume-type internal-combustion engine to use in road vehicles, an increased amount of attention has been paid recently to the problem of adopting steam to the same purpose. Louis L. Scott, chief engineer, Standard Engineering Company, St. Louis, Mo., presented a description of a Steam Automotive System which it is said has already been applied both to passenger cars and to trucks.

L. H. Pomeroy, consulting engineer, Cleveland, Ohio, discussed the trend of automotive-engine design in the light of the application of modern views of gasoline-engine thermodynamics, and noted recent improvements in mechanical efficiency, in engine balancing, in carburetion and the progress which has been made in the utilization of low-grade fuels.

Of special interest were also the following: Aluminum Piston Design, E. G. Dunn; The Measurement of Vehicle Vibrations, Benjamin Liebowitz; Needs in Engine Design, Frank H. Trego; Bettering the Efficiency of Existing Engines, Hugo C. Gibson; Mixture Requirements of Automotive Engines, O. C. Berry; Springs and Spring Suspensions, E. Favary; The Velocity of Flame Propagation in Engine Cylinders, R. K. Honoman and Donald McKenzie; and Composite Fuels, Joseph E. Pogue.

The report of the Iron and Steel Division proposed specifications for low-tungsten steel for inlet and exhaust valves, nickel steel for case-hardened parts, malleable-iron castings for general automotive purposes, and high-chromium steel for exhaust valves in aeroplane engines. The composition recommended for low-tungsten steel expressed in percentage was: carbon, 0.50 to 0.70; manganese, not to exceed 0.30; phosphorus, not to exceed 0.035; sulphur, not to exceed 0.035; chromium, 0.50 to 2.00. Malleable castings were specified to be produced by air-furnace, open-hearth, or electric-furnace process; the minimum tensile strength permitted was 45,000 lb. per sq. in. and a minimum elongation of 7.5 per cent in 2 in. The suggested composition in percentage for high-chromium carbon steel was: carbon, 0.20 to 0.40; manganese, not to exceed 0.50; phosphorus, not to exceed 0.035; sulphur, not to exceed 0.035; chromium, 11.50 to 14.00; silicon, not to exceed 0.30.

## New York Automobile Show

The New York Automobile Show, held at the Grand Central Palace in the week of January 3 to January 10, left a mixed impression on an engineer who tried to gage the state of the industry from the exhibits.

The first impression was decidedly encouraging. Both the exhibits and the attendance at the show indicated a thoroughly healthy state of the industry. Practically all the old companies were represented, and there were a considerable number of newcomers who had either made good already, or who gave fair promise of doing so as soon as they had had time enough to arrive at this result.

The art of exhibiting automobiles has made a big advance since one or two years ago. The general disposition of the exhibits this year was good, and there was far less crowding than marked the exhibits of the previous years. More sectional models than ever were shown, operated by electric motors so as to give a chance to the public and the engineers to see the inside construction. This latter was a rather unexpected feature as in the last few years the study of engine development has been such that the ability of the engine to perform is now taken for granted. On the other hand, however, it may be that the technical education of the public has proceeded to such a point that a larger number than ever want to know the reason why and refuse to take anything for granted in mechanical lines.

More and more attention is being paid to body refinements, and the coach work of the cars shown at the Grand Central Palace exhibited a gratifying high form of development.

All this is highly encouraging, but some of the promises of the past two years do not seem to have been fulfilled, at least as far as one may judge from what was shown at the Grand Central Palace.

For nearly two years the automotive industry was in the service of the Government, engaged in assisting it in the strenuous work of building up in record time the great American war machine. This necessarily forced automobile engineers into entirely new lines of work. Some of them made shells, others aeroplanes and aeroplane motors; still others the fine instruments needed for the Ordnance and Navy Departments. It was confidently expected that this would bring a flood of new ideas into the automobile field just as it did in Europe, and from this point of view the show was to a certain extent disappointing.

There were exhibited no really new developments. The engines, the chassis construction (with some exceptions), the accessories still follow the conventional lines, and, notwithstanding even the impending shortage of gasoline, nothing at the show indicated that the industry is anything like prepared to meet this great condition.

It would be unfair, however, to exaggerate this fact, or to attach too great importance to it, for two reasons. In the first place, during the year and a half elapsed since the war the American automobile industry has gone through a period of tremendous strain. Following the great task of reconverting the industry back to the peace basis were the grave labor disturbances both in the automobile plants themselves, and still more so in the accessory plants supplying automobile plants with castings, bodies and parts, which created conditions anything but favorable to the undertaking of new developments on a large scale.

That in the face of all this the automobile industry has been able not only to meet the demands of the market, but to bring into the product a number of minor improvements, clearly shows the great vitality of the industry and the genius of the men directing it, and it would have been difficult to expect basic developments under such conditions in such a comparatively short time. That important research work is going on in practically all the larger companies is an open secret, but the results of this work were not shown at the Grand Central Palace, and from this point of view it cannot be said that the show represented the actual state of the industry.

While, however, no radical improvements were shown, a trained eye could easily discover the influence of war work in many directions. The finish of parts, the machining, and especially the attention paid to the balancing of moving parts, is far superior to anything that we have seen in the industry in the past.

What has been said about the Passenger Car Show at the Grand Central Palace, largely applies also to the Motor Truck Show which was going on simultaneously at the Jerome Avenue Armory.

Of the minor improvements, the following may be noted:

At the Passenger Car Show the spring suspension was employed in such a manner that a spring base of 130 in. is secured with a wheel base of only 100 in.

At the Commercial Car Show, the Shacht Motor Car Company exhibited a truck with a 10-speed transmission which is secured by using a regular five-speed transmission (four ahead and one reverse) and a sub-transmission doubling the range of the main transmission. So far this arrangement has been applied to 5-ton trucks only where apparently there may be the greatest demand for it.

The fundamental impression left by the thousands of exhibits at the show would indicate that the industry is a perfectly healthy one and that greater things may be confidently looked forward to in the very near future in the way of mechanical road transport.

This is of importance not only to the automobile industry generally but to the country at large, as transportation is a measure of the progress of civilization.

## Anatole Mallet

Anatole Mallet, Honorary Member of The American Society of Mechanical Engineers, died in Nice, France, in October, 1919. He was one of the few men whose name became the designation of a standard type of apparatus in a great industry. Born in 1837 at Carouge, and graduated in 1858 from the Central School of Arts and Manufactures in Paris, Mr. Mallet devoted all his attention for a number of years to problems in civil engineering. He was first connected with the Bureau of Direction of the General Company of Railroad Materials in France, and subsequently with the work on the Suez Canal. In 1864 he was engineer for the company which undertook the dredging of ports of Italy.

In 1867 he engaged for the first time in mechanical engineering, giving particular attention to steam engines with double

ANATOLE MALLET

expansion. The first application of this system to locomotives was made in 1876, when he introduced the first two-cylinder compound locomotive, which operated on the line from Bayonne to Biarritz. A fuel economy 20 per cent superior to that given by the standard types of the time was attained, which at once placed the inventor in the foremost ranks of locomotive designers.

The great success of the compound locomotive led to a material increase in the size of the tractive unit and to the development successively of three- and four-cylinder compound locomotives. In this way it became evident that the limit of size of a locomotive of rigid construction, especially on lines with sharp curves, would soon be reached, and the problem arose of building a locomotive of still larger size which would have the necessary flexibility. This problem was solved by Mallet in the design of the articulated locomotive, an invention which made his name familiar to every railroad engineer throughout the world. The most powerful locomotives now in existence are of the Mallet articulated type.

He was a member of the Society of Civil Engineers of France, The Society for the Encouragement of National Industry of France, and The Franklin Institute of Philadelphia. The French Society of Civil Engineers awarded him the Schneider prize in

1902, and the annual prizes in 1909 and 1911. He was made a Knight of the Legion of Honor in 1885 and promoted to Officer in 1905. The Institution of Mechanical Engineers of London awarded him a gold medal in 1915.

In addition to carrying on important engineering work, Mr. Mallet took an active part in the work of the French Society of Civil Engineers. From 1880 to within a few months of his death he was editor of the *Chronicle* of the Bulletin of the Society and furnished it with numerous technical notes and important memoirs, the last of which, treating of The Practical Evolution of the Steam Engine, earned for him the honors conferred by the Society.

## Death of the President of the Massachusetts Institute of Technology

Richard C. Maclaurin, President of the Massachusetts Institute of Technology, died of pneumonia at his home in Cambridge, Mass., on January 15. He was only 49 years old, but had gained an international reputation, not only as an educator and an administrator of large affairs, but as a physicist, a mathematician and a jurist.

Dr. Maclaurin was born in Edinburgh in 1870. His early boy-

RICHARD C. MACLAURIN

hood was spent in New Zealand, whence he returned to England to complete his preliminary education in English schools. He later was graduated from St. John's College of the University of Cambridge, where he also received the advanced degree of Master of Arts, the thesis work for which was in higher mathematics.

He next spent several months in the United States and Canada studying educational institutions. Again returning to England he reentered Cambridge, this time to study law, and was awarded the McMahon Law Studentship, the most highly valued in the university for law students.

In 1898 Dr. Maclaurin was appointed professor of mathematics in the University of New Zealand, became a trustee of the university, and took an active part in the organization of technical education in the colony. In 1903 he became Dean of the Faculty of Law in the university, which office he held for four years. In 1907 he was invited to take the chair of mathematical physics at Columbia University, New York, and a year later was made head of the department of physics.

In 1898 the degree of Doctor of Science was conferred upon Professor Maclaurin by Cambridge University for his researches in pure science, and again in 1904 he was honored with the degree Doctor of Laws by the same university for his achievements in the study of law.

In 1908 Dr. Maclaurin was appointed president of the Massachusetts Institute of Technology at a time when its finances were low, its buildings inadequate, and the call for the education at this institution of students from all over the world was very great. The new president succeeded in drawing together into a unified, enthusiastic body the corporation and faculty of the institute, and the alumni and students. By concerted action the movement was started which resulted in the new and greater Technology now located in its magnificent buildings on the Charles River in Cambridge, Mass. One of the fruits of this movement was a gift by T. Coleman du Pont of \$500,000 toward the purchase of the site for the buildings. How Dr. Maclaurin, backed by the alumni, succeeded in raising the additional funds needed for the completion of the plans for expansion is told in another article in this number. The culmination of this was the announcement at a jubilee dinner by the alumni on January 10 of the success of the campaign for a \$4,000,000 endowment, supplemented by a gift of an equal amount by George Eastman of the Eastman Kodak Company. Just previously, however, Dr. Maclaurin had been stricken by illness, and it was not permitted to him to tell the alumni personally of this greatest achievement of his life. A few days later he died—indeed a tragedy, his death coming at the height of his career, just as he had completed the foundation for the great educational work which the institute is destined to accomplish with its splendid equipment.

## AN IMPROVED WEIR FOR GAGING IN OPEN CHANNELS

(Continued from page 88)

One word more, however, the writer allows himself in relation to the formulae for weir discharge. It had been his intention not to evolve any formula, but to present the result of his experiments in the form of a table, arranged somewhat as are tables of logarithms, so that quantities could always be read at a glance from the data observed. No one cares for the formulae by means of which logarithms are computed; their use would not be furthered by a study of them. No more need a Power Test Code contain formulae for weir discharge; a table would answer its purposes more fittingly.

But the exceeding simplicity of the weir formula appurtenant to the form of weir herein presented upset this plan. Such a weir does not need so much as a table to look up or to compute its discharge. All one has to do is to measure the length of the weir and then multiply it by 5.5 and by the difference in head.

But there remains the question, why 5.5? Why not 20, or any other quantity? And for the mitigation of the stated laudable curiosity, further experiments will no doubt be undertaken in the course of time; and much ink of disquisition may yet be set adrift.

## THE TESTING OF FARM TRACTORS

(Continued from page 102)

as a machine for converting gasoline into tractive force would remain as determined by the laboratory tests. These tests may be denominated consumer's tests.

The first and its corresponding field experiments will have determined the overall efficiency of the tractor as a power machine.

The second will differentiate these results and distribute the various factors of efficiency or inefficiency throughout the machine. It will serve to separate the performance of the engine from that of the transmission and other moving parts, and in so doing will perhaps be more satisfactory to the manufacturer. This we may denominate a producer's test.

# EMPLOYEES' REPRESENTATION IN MANAGEMENT OF INDUSTRY

The Economic Questions Involved, as Summarized by Dr. Royal Meeker, U. S. Commissioner of Labor Statistics, at Conference on Industrial Relations Held at Chicago. Together with Other Discussion

THE annual convention of the American Economic Association was held in Chicago on December 29 to 31 concurrently with those of the American Association for Labor Legislation and the American Sociological Society. The question of industrial unrest formed the topic of a great number of the addresses in the three programs. Particularly at a joint session of the Association for Labor Legislation and the Economic Association the discussion of this question was brought to a focus by Dr. Royal Meeker, United States Commissioner of Labor Statistics, who, in his address on Employees' Representation in the Management of Industry, asserted that neither the English Whitley scheme nor the various plans which have been introduced in American industries constitute anything more than an initial experiment in the direction of a solution of industrial unrest.

In Great Britain the Whitley system of organizing industries into national and district joint industrial councils and works committees was adopted at the instance of the Government. Up to date, national joint industrial councils have been set up in some fifty industries, besides the councils established in the Government departments for both manual and clerical employees. These national joint councils, according to Dr. Meeker, are analogous to the roof of a house suspended in mid-air with no supporting side walls or foundations upon which to rest. Only three industries have set up complete Whitley systems of joint industrial representation of employers and employees with a national council and district councils for the industry and works committees for individual shops, and these three industries are relatively insignificant, namely, match, rubber and pottery manufacturing.

Dr. Meeker divided the different types of shop committees and work councils in this country into three distinct groups: (1) closed-shop committees of union workers chosen exclusively by union men affiliated with national or international unions; (2) open-shop committees composed of workers chosen by the votes of all workers who have been employed in the shop a required length of time; (3) open-closed-shop committees chosen by all workers qualified to vote in a shop that is closed against trade unions and which may or may not have a local plant or corporation organization of the workers. There is, in fact, little fundamental variation, he said, in the published statements of the objects sought and the plans of organization as between group and group.

Comparing the different views of Americans and of the British, Dr. Meeker pointed out that respecting labor organization the position of organized employers and employees is exactly reversed in Great Britain. We today are where the British were about thirty years ago. The question of national unions versus plant unions was fought out in Great Britain and won by the workers. British employers were obliged to accept the result and bargained collectively with the representatives of the national unions. During the war the workers rebelled against this system, insisting that wages, hours and shop conditions should be negotiated for each shop by the local shop committees. The employers stood up valiantly for the established order, and insisted that they would have nothing to do with local shop committees, but would bargain collectively only with truly responsible and representative bodies, the executives of the national trade unions. American employers, equally valiant for the established order, will have nothing to do with irresponsible, unrepresentative officials of national trade unions and insist on bargaining collectively with representatives of the workers who know the local situation and who are chosen from the shop where a dispute is pending. One of the biggest questions to be settled, in Dr. Meeker's opinion, is whether employees' representation is to be local and under the direct control and domination of the employer, or whether it is to be nation- or world-wide and under the control of the workers themselves, or whether the general public

will insist on being a party to every collective agreement so as to prevent the employers and employees from agreeing too agreeably and charging the bill to the ultimate consumer.

If workers are to be admitted to actual participation, Dr. Meeker suggested they must participate to some extent in the losses as well as the gains of industry. A practical method of payment would be to guarantee for each position a minimum wage which must be paid regardless of any losses which the business may suffer. In addition to the minimum, a bonus should be provided varying according to the contribution of the workers in cutting down labor costs, in reducing costs of management, in decreasing spoilage of material, in decreasing wear and tear on machines and tools, in improving quality of product, in increasing business, or in any other way. This would obviate the objection to most bonus schemes that the worker is penalized or rewarded for the inefficiency or the good judgment of the managers.

Labor unrest, in the present-day meaning of the term, is, in Dr. Meeker's opinion, a natural and inevitable result of the industrial revolution, machine production, absentee ownership of industrial establishments, and the centering of industrial management in the hands of managers of finance whose offices are in the big banks and office buildings of the centers of finance and trade. Strikes in the modern sense were practically unknown until industrial units had grown to such a size as to erect formidable barriers between the workers on the one side and the responsible owners and managers on the other. Lack of interest in work, he said, grows out of absentee ownership. The absent industrial landlords, interested only or principally in dividends, have employed experts, scientific managers, to produce a substitute for the old-time workman's interest in his work. The theoretical ideal of maximum output with minimum expenditure of effort which can be figured out by mathematical formulae and pictured on charts, is never attained in practice. A much more imperfect layout, which leaves much to the ingenuity and initiative of the individual workmen, in practice always achieves better results.

The present-day movement for industrial democracy, Dr. Meeker continued, is a partial recognition of the fundamental psychological phenomenon that industrial fatigue is not simply an engineering question to be stated mathematically in foot-pounds per hour or even a physiological question having to do with calories used up in the body. Work is hard primarily because it is uninteresting and monotonous, or easy because it demands ingenuity or skill. Paradoxical as it seems, the way to make work easier is to make it harder by requiring more of the workmen. In so far as scientific management has resulted in merely breaking processes up into component parts, segregating so far as possible the purely muscular and mechanical operations from the creative and planning functions, so-called "efficiency" has resulted in the most disastrous inefficiency.

Willard E. Hotchkiss, Chicago, took issue with various of Dr. Meeker's remarks and maintained that it has not been established as a fact that the workers object to repetitive jobs. Economists, he stated, have created a complete literature on the labor problem which is based on *a priori* conclusions. In his opinion little progress will be made in the direction of a solution of our labor difficulties until principles are worked out by inductive reasoning.

Prof. Ira B. Cross, University of California, raised the question whether the introduction of works councils did not constitute a dangerous economic policy. He cited the circumstance which attended the introduction of the works-council plan in a large American industry. The workmen, who were doubtful as to the advantages of the scheme, asked the advice of radical labor leaders and were told to support it on the theory that eventually it, in conjunction with similar councils in other industries, would form the basis for establishing a soviet form of government.

Prof. Frank W. Blackmar, University of Kansas, in an address on A Working Democracy, emphasized that neither an autocracy of capital nor an autocracy of labor can be permanently successful. A similar idea was discussed by A. W. Small, University of Chicago, who, in a paper on Democracy and Labor, read before the Sociological Society, described "laborocracy" as being as objectionable as any other kind of autocracy, and as inevitably doomed.

An optimistic view of the labor situation was presented by Matthew Woll, vice-president of the American Federation of Labor. He addressed the Sociological Society on Labor and Democracy, and the Economics Association on Labor and Immigration Questions. He asserted that the bulk of organized labor is loyal to America and its institutions and observed that while there

have been a few spectacular labor disputes, like the steel strike and the coal strike, there have also been thousands of readjustments of wages and working conditions through direct negotiations between employers and organized labor without strikes.

John A. Fitch of *The Survey*, and S. K. Ratcliffe, a well-known English journalist, delivered interesting talks at a joint session of the Association for Labor Legislation and the Sociological Society, on the general subject of Democracy and Industrial Life.

Another general subject which was given much attention was the prospect for international labor legislation.

A more extensive account of these conventions is given in *Iron Age* for January 8, 1920, from which these notes have been prepared.

## GOVERNMENT ACTIVITIES IN ENGINEERING

*Notes Contributed by The National Service Committee of Engineering Council<sup>1</sup>*

### A New Board of Surveys and Maps

**A**N executive order recently issued by President Wilson creates a new Board of Surveys and Maps, the purpose of which shall be to coordinate the activities of the various map-making agencies of the Government, to standardize results and to avoid unnecessary duplication of work. This order is the outcome of a suggestion which Engineering Council made to President Wilson in a letter dated July 1, 1919, which pointed out that the official map work of the United States was being prosecuted by twelve separate and distinct Federal agencies, the majority of which are making maps for special purposes, and which are of little value for any other purposes. Furthermore, some states, counties, cities, and private organizations are also engaged in this work and since each of the Federal agencies and the others above mentioned follows methods developed in its own surveys, the result is precisely that which might be expected. There is no agency in the United States which has authority to coordinate the work.

The Council therefore advised the creation of a "Board of Surveys and Maps" consisting of a representative from each of the present Federal map-making agencies, together with representatives from well-qualified map-using agencies, which would be vested with authority to work out a plan of standardization and coordination of the work of the Government.

This letter was referred by the President to the Secretary of War with the request that a conference of representatives of the twelve map-making agencies named by Engineering Council be called to consider the suggestion in its several practical aspects. Representatives of these agencies and of the Forest Service and U. S. Hydrographic Office accordingly held a series of conferences at Washington, D. C., from September 15 to 29, inclusive, and the following engineering and scientific societies were invited to send representatives to the meetings to present their needs:

#### Engineering Council

- The American Society of Civil Engineers
- The American Institute of Mining and Metallurgical Engineers
- The American Society of Mechanical Engineers
- The American Institute of Electrical Engineers
- The American Association of State Geologists
- The American Association of State Highway Officials
- The National Research Council
- The Association of American Geographers
- The American Geographical Society
- The Geological Society of America
- The National Geographic Society

Ten of these organizations were represented at the conference on September 22, but since the time available was not sufficient to formulate and present their views during the conference, it was

agreed that the above-named organizations would present their recommendations to the permanent body proposed by the conference.

The report of the conference, submitted to the President through the Secretary of War on September 30, 1919, includes a general survey of the subject; a statement of the map needs and of the map-making activities of each of the fourteen organizations represented at the conference; the practical program outlined by the Interdepartmental Committee on Aerial Surveying; suggestions for consideration by the proposed Board of Surveys and Maps; and estimates for the completion of primary control of the United States by the U. S. Coast and Geodetic Survey and for the completion of the topographic mapping by the U. S. Geological Survey.

The Board of Surveys and Maps, according to the executive order, will be composed of representatives of the fourteen organizations represented at the conference. The order further provides that the individual members of this Board shall be appointed by the chiefs of the various organizations named and shall serve without additional compensation.

The Board is also directed to make recommendations to the several Departments, or to the President, for the purpose of coordinating all map-making and surveying activities of the Government and to settle all questions at issue between executive departments relating to surveys and maps insofar as their decisions do not conflict with existing laws.

The Board is authorized to establish a central information office in the U. S. Geological Survey for the purpose of collecting, classifying and furnishing to the public information concerning all map and survey data available.

A permanent organization of the Board was effected on January 13 when representatives from each of the Departments met and elected O. C. Merrill, Chairman (Chief Engineer, Forest Service, Department of Agriculture); William Bowie, Vice-Chairman (Chief, Division of Geodesy, Coast and Geodetic Survey, Department of Commerce); and Colonel C. H. Birdseye, Secretary (Chief Geographer, Geological Survey of the Department of Interior).

It is hoped that this concentration of mapping work will permit larger proportionate appropriations for the country's mapping program under the direction of the Geological Survey. In bringing this matter to the attention of the President, Engineering Council realized the great value of making reliable maps of the whole country available to every branch of the engineering profession in the simplest and most direct way. This will be accomplished through the central information office provided in the Geological Survey to receive and distribute Government and public map data. Thus, if proper appropriations can be obtained and put to work under the Geological Survey, the engineers of the country as well as the Government departments will be greatly benefited.

In this connection it is pertinent to state that the National Service Committee of Engineering Council in cooperation with all state geologists are urging prominent engineers in every congressional district to bring pressure to bear upon their congress-

<sup>1</sup>Engineering Council is an organization of national technical societies created to consider matters of common concern to engineers as well as those of public welfare in which the profession is interested. The headquarters of Engineering Council are located in the Engineering Societies Building, 29 West 34th Street, New York City. The Council also maintains a Washington office with M. G. Leighton, chairman of the National Service Committee in charge. This office is in the McLaughlin Building, 10th and G Streets, Washington, D. C. The officers of Engineering Council are: J. Park Channing, Chairman; Alfred D. Pflin, Secretary.

men to vote sufficient funds for topographic mapping. This has been accomplished by selecting a prominent engineer—members of the Founder Societies—in each congressional district and urging them by direct appeal to request their senators and representative to support a \$600,000 appropriation for topographic mapping.

The state geologists have cooperated by sending these engineers complete information of the local conditions, so that they may be thoroughly conversant with their "back-home" requirements, and thus be more forceful with their men in Congress. Further, most of the state geologists are endeavoring to get increased state appropriations for this important work, which will have to be matched by an equal Federal appropriation in most cases before they become available for expenditure.

The estimates submitted by the Secretary of the Interior call for an increased mapping program to cost \$600,000 annually, instead of \$500,000 which was last year's estimate. It will be recalled that the last Sundry Civil Appropriation Bill provided \$375,000 for topographic mapping, which was less by \$50,000 than prewar annual appropriations for this work. This year's estimate contemplates a program that will complete topographic mapping in twelve years instead of the one hundred years which will be required if the old appropriation is not increased.

### Water Power Bill Passes Senate

Although it was stated in the last issue of MECHANICAL ENGINEERING that the Senate, during its next session, would take up, and possibly dispose of, several bills of interest to engineers, such action has not, up to the time of going to press, taken place.

The Senate, upon reconvening on January 5, after the usual holiday session, first devoted its attention to the Water-Power Bill, discussion of which lasted nearly a week for the debate both on the bill itself and on many of its amendments was very active. The bill finally passed the Senate with a majority of three to one, substantially as passed by the House, except as to certain conditions of renewal to take effect after 50 years' license. In reporting the bill to the Senate the Committee explained and clarified the definitions of "reservations," "navigable waters" and "costs." A proportionate license fee not exceeding twenty-five cents per horsepower is proposed, which is to defray costs of the administration of the act. Fair rentals are to be charged for Government dams and other Government property on water-power sites. The bill also provides that in case the United States does not exercise the right to take over the works, the license tendered shall be "on reasonable terms" and "which is accepted" by the original or the new licensee. This provision was thought necessary to make it certain that capital would invest under the law. A provision for severance damages also appears in the bill.

This bill now goes to a committee composed of members from both the House and Senate. This is for the purpose of settling on points of difference. The Senate is represented by Senators Jones, Nelson, Smoot and Fall (Republicans) and Bankhead and Myers (Democrats). The House conferees have not as yet been appointed. It is not expected, however, that further delay will be occasioned, and that not more than two weeks will be occupied in getting the bill through this Joint Conference Committee.

### Technical Work at Bureau of Standards

Bulletins dated January 9 on the progress of experimental work that has been started at the Bureau of Standards are as follows: (1) Accuracy of Electrical Measuring Instruments; (2) Electron Tubes in Radio Telephone Transmitting Sets; (3) Recent Radio Publications; (4) Industrial Safety Standards; (5) Measurement of Thermal Expansion of Various Materials; (6) Service Tests of Concrete Floor Treatments; (7) Consistency and Time of Set of Next Cement Determined by New Method; (8) Slag as an Aggregate for Concrete; (9) Flat-Slab Investigation; (10) Manufacture of Automobile Crankshafts; (11) Investigation of Electric Welding; and (12) of Chilled-Iron Car Wheels.

Because of the current nature of these investigations the results are not generally put in printed form, but complete data on

the results of the work to date are always available on application to the Bureau of Standards or the National Service Committee in the Washington office of Engineering Council.

### Colonel Beach New Chief of Engineer Corps

Colonel Lansing H. Beach, U. S. A., has been appointed Chief of Engineers, replacing General William M. Black, retired. Colonel Beach's appointment came as a complete surprise to many, as he had not been publicly mentioned for the place. He is a native of Iowa and a graduate of West Point and has held the rank of Colonel since 1913. While Colonel Beach is best known for the work he has done in connection with Mississippi River projects, he has had the varied service which comes to all Engineer Corps officers who have spent most of their lives in its service. He has done extensive engineering work on Great Lakes projects and was in charge of the important improvements of the harbors of Baltimore and Jacksonville. More recently he has been stationed at Cincinnati in charge of the construction of the system of locks and movable dams being constructed in the Ohio River. Colonel Beach has been prominently identified with the development of inland waterways, as a member of the Mississippi River Commission and as a member of the Board of Engineers for Rivers and Harbors and as an advisor to the Waterways Division of Railroad Administration.

### TAYLOR SYSTEM IN GERMANY

The following advertisement of a firm of efficiency engineers taken from a German trade paper, gives a pithy expression of the benefits claimed for scientific management. The translation of the advertisement is also given in similar form.

#### Für Arbeitgeber und Arbeitnehmer:

Erhöhung des Einkommens und der Leistungsfähigkeit. Einschränkung jedes überflüssigen Kräfteverbrauchs.

Der einzige Weg zur Erhöhung der Löhne bei Verminderung der Produktionskosten.

#### Für die gesamte Wirtschaft:

Erhöhung der Produktion mit den jetzigen Einrichtungen.

Qualitäts-Erzeugung und Steigerung der Leistungsfähigkeit bei Verminderung der Erzeugungskosten. Erhöhung des tatsächlichen Arbeitswertes durch ergiebigeren Ausnutzung aller aufgewendeten Mittel: Zeit, Kraft, Material und Geld.

#### Für den Wiederaufbau Deutschlands die Rettung!

Das ist das Taylor-System!

#### The Taylor System Means

##### To the Employer and Employee:

Higher Income and Efficiency  
Reduction of Unnecessary Consumption of Effort  
The Only Way to Raise Wages and at the Same Time Reduce Cost of Production.

##### For the Entire Industrial System:

Increase of Production With Now Available Facilities  
Quality Production and Increase of Efficiency at Lower Cost of Production  
Increase of the Actual Value of Work by a More Efficient Utilization of Employed Means, Namely, Time, Effort, Material and Money.

##### For the Reconstruction of Germany—Salvation.

# NATIONAL DEPARTMENT OF PUBLIC WORKS ASSOCIATION HOLDS SECOND CONVENTION

## Engineers Urge Congress To Pass Jones-Reavis Bill Consolidating Federal Public Works

NATIONAL interest in the bill now before Congress to replace the present Department of the Interior by a National Department of Public Works, and thus bring under one bureau all the engineering activities of the Government, was greatly intensified by a two-days' conference of the National Department of Public Works Association held at the Willard Hotel, Washington, D. C., January 13 and 14. Ninety-five delegates representing the leading engineering societies and organizations of the country, with a total combined membership of nearly 90,000, took part in the discussions and proceedings of the conference.

Four sessions were held. These were chiefly given over to reports of officers and committees and discussion of the Public Works Department bill now before Congress. A communication from Governor Lowden of Illinois dealing with the organization of the public works in that state was presented, and Representative Reavis, one of the authors of the bill, and Brigadier-General R. C. Marshall, chief of the Construction Division of the United States Army, also addressed the convention.

General Marshall pointed out that there are at present 27 separate and distinct Federal agencies engaged in the construction of public buildings, 18 in building roads, and 18 in work relating to hydraulics, river and harbor work. He was accordingly of the opinion that a Department of Public Works could accomplish a most constructive step in the history of Government work by placing all Federal construction under control of a single bureau with a single method of accounting and a single bureau of purchase.

M. O. Leighton, chairman of the Executive Committee, opened the convention by briefly reviewing the history of the Association since the inception of the movement by Engineering Council at a meeting held last April. As originally planned the Association was made up solely of technical men, but the movement has since become so general that its supporters are now convinced that it should have active backing from those outside the profession. Chairman Leighton expressed these sentiments in his opening address as follows:

We here assembled are asking Congress to do the obvious thing. Give the Government a business-like organization. Coordinate the functions so that the processes of Government business shall dovetail. Cut out the wastes and the duplications. Abolish the rivalry between departments. We advocate a Department of Public Works not merely to secure technical symmetry in our Federal organization, desirable as that end may be, but our advocacy in its essential features is an attempt to stop some of the waste.

When this organization was set up at Chicago I think that none of us—certainly not the speaker—had an adequate idea of the scope of the movement. We saw a loose and inefficient public works organization, divided and subdivided into many different provinces. As technical men we knew how organically wrong that was. Of the wastes and inefficiencies we were well aware. With the necessity for a coordinated structure by virtue of which the technical and semi-technical fields of the Government could be rendered efficient and business-like we were profoundly impressed. But that our effort, our idea, our legislative bill would become the cornerstone of a structure embodying efficiency on all Departments of Government we could hardly foresee. As an organization our effort is still focused on a Department of Public Works and that alone. But we realize that with that principle established—that example set—reform in other provinces of Government business activity will occur by the mere logic of events. We are pioneers.

This is the reason why our project for a Department of Public Works strikes straight home to the business man, the manufacturer, the contractor, and the merchant, all of whom are represented here today. The technical men who met at Chicago last April to set up this organization built better than they knew. While the project retains all the virtues that appealed to us when it was launched—of technical excellence, of rational Government organization, of economy and efficiency, we now see that it reaches to national and to business prosperity, to the fiscal welfare of the nation, to the individual welfare of the productive business.

We may as well recognize and admit the fact that individual initiative in America will not continue to be that spontaneous thing that it has been in the past if the rewards are to be divided and a part of them are to be wasted in the support of a chaotic Government business

organization. The burdens of every business organization in the country are magnified by Government business inefficiency. We want no good and proper thing to be withheld from our Government nor in turn by our Government.

References to the efforts of engineering organizations to create a Department of Public Works have frequently been made in the columns of MECHANICAL ENGINEERING. The bill which creates this new Department is commonly known as the Jones-Reavis Bill, and the details of the changes which it proposes in the executive machinery of the Government were discussed in the August issue, page 709. Briefly the bill creates a Department of Public Works which is to replace the Department of the Interior and thus assemble under one head all the engineering activities of the Government. Such bureaus of the Department of the Interior as are of a non-engineering character will be transferred to existing appropriate departments.

The first convention in this movement was held in Chicago last April, and since that time various state committees have been at work within their own districts. A roll call of these various state committees held during the convention showed that considerable effective work has been done, chiefly, however, in the southern and western states. Two states reported that their entire congressional representation had pledged their support of the bill. The eastern states, and particularly those which represent the large industrial centers have, however, made but little progress toward obtaining congressional support. This condition of affairs was not altogether expected, and in the opinion of many, considerable effort will be necessary to overcome the opportunities thus lost.

Following the roll-call the Jones-Reavis Bill itself was discussed. The chief objections centered around Section 3 which provided for the transfer of the Bureaus of Education, Pensions, Indian Affairs and other similar non-engineering bureaus of the Department of the Interior to existing department of the Government. In order to place before the public its position on this and other controversial section of the bill the convention adopted the following resolution defining its position:

- 1 The National Public Works Department Association must, under its articles of organization, confine its efforts solely to the creation of a Department of Public Works.

- 2 Section 3 of H. R. 6649-S. 2232 (the Jones-Reavis Bill) has nothing to do with public works. The only reason for its presence in the bill is that some departmental disposition must be made of the non-engineering bureaus in the Interior Department.

- 3 It is manifest that the numerous organizations which become affiliated under the name of National Public Works Department Association for a common public-works purposes do not, by so doing, commit themselves with respect to any other question, national or otherwise. Therefore each affiliated organization may have and is entitled to express its views as to said Section 3 of the bill without in any way qualifying its approval of the remainder of the bill.

- 4 The National Public Works Department Association, as such, is therefore unable either to approve or to disapprove the specific assignments of bureaus in the said Section 3, and in advocating the bill before committees of Congress the agents of this Association are to be instructed to present this fact in an unmistakable way.

- 5 The National Public Works Department Association suggests to all affiliated organizations that they present to Congress their own individual views with respect to said Section 3, either through the legislative agents of this Association or otherwise.

- 6 The officers and directors of this Association are instructed to have the foregoing statements printed in suitable form and circulated as one of the campaign documents issued in support of this movement.

The second day of the conference was largely devoted to interviews with senators and congressmen, committees representing the several states having been appointed for this purpose the day previous. Reports of these interviews indicate that the proposed bill will doubtless be favorably reported, although it must not be inferred that success is altogether assured. On the contrary, the task of securing sufficient support to finally pass the bill has only just begun, and an undue optimism at this time may result in failure. The widest publicity possible should accord-

ingly be given the measure and every engineer should make it a personal matter to lend his support to this exceedingly important bill.

The Committee on New Organization, of which Calvin W. Rice, Secretary of The American Society of Mechanical Engineers, is chairman, rendered a report in which it recommended that the scope of the appeal of the association be enlarged to include the business, professional and social bodies and that all such activities be accorded executive representation in the movement.

The Committee also suggested that there be a committee of the Association in every state; that each state committee use every existing organization which is in any way enlisted by this movement.

The Committee stated that while the present organization of

the Association has been adequate and admirable up to the present time it should nevertheless be enlarged as indicated. What it needs is popular support in effort and in subscription.

The knowledge that the present officers have of the needs of the work should be accepted and such expansion should be granted as the officers and Executive Committee may recommend.

During the final session of the convention the financial needs of the Association were discussed at some length, and it was made very evident to those present that, if the Association was to continue, this issue must be met and settled. Heretofore the various member societies of the Association have contributed but little, the expenses of the work being largely met by individual subscriptions. The Committee recommended that each society be asked to assess its members at the rate of one dollar per man.

## ENGINEERING FOUNDATION REPORTS PROGRESS IN RESEARCH

THE second formal publication of the Engineering Foundation, scheduled to appear in October but delayed by the recent printers' strike in New York, has just been issued. Engineering Foundation is one of the three departments of the United Engineering Society, and was made possible by the presentation to that organization of a sum of money as a trust fund, the interest of which is to be used in the promotion of engineering research. This gift came from Ambrose P. Swasey, past-president and honorary member of The American Society of Mechanical Engineers. In 1914, in fulfillment of his desire to advance the work of the engineer and add to the accumulated facts which serve to guide him in his undertakings, he gave the United Engineering Society \$200,000, the income of which should be used "for the furtherance of research in science and engineering, or for the advancement in any other manner of the profession of engineering and the good of mankind." In September 1918 Mr. Swasey added \$100,000 to the endowment, making the present total \$300,000.

The organization meeting of the Engineering Foundation Board was held on April 15, 1915. As at first constituted, the Board had eleven members, elected by United Engineering Society and each serving for a term of three years or less. By amendment of the By-Laws of United Engineering Society, April 25, 1918, the Board was enlarged to sixteen members, and by this amendment an executive committee of five members was also provided.

The Engineering Foundation Board is charged with the responsibility of administering funds placed at its disposal. It supports no project the merits of which have not been demonstrated by competent inquiry. In the development of such inquiry it is fortunate in possessing the cooperation of the National Research Council, an organization having world-wide scientific affiliations. While the Engineering Foundation Board reserves to itself the right to choose, initiate, and conduct under its own immediate direction such researches as may commend themselves to its membership, it is at the present time making extensive use of certain channels established by the National Research Council, notably the Council's Division of Engineering.

The National Research Council is an organization of American scientists, engineers and educators, established in April 1916 under the Congressional charter of the National Academy of Sciences, given in 1863. It comprises representatives of national scientific and technical societies, chiefs of technical bureaus of the Army and Navy, heads of governmental bureaus engaged in scientific research, representatives of other research organizations, and other persons whose aid may advance the objects of the Council. The Council is organized in thirteen divisions of two classes, six dealing with the more general relations and activities of the Council and seven with science and technology. The Division of Engineering, under this second class, includes twenty-eight members, at least five of whom are members of the Engineering Foundation, and one of whom is the Chairman of that body. A more detailed history of the National Research Council will be found in MECHANICAL ENGINEERING for July 1919, p. 631.

In June 1916 the Engineering Foundation Board decided to devote its resources to the National Research Council for one year,

beginning September 1916. The close cooperation between the two organizations which resulted from this decision was found to be so mutually helpful that at a meeting of the Foundation Board in September 1917 it was resolved "to continue the cooperation between the two bodies in all practicable ways that may be now, or may become, mutually available, such ways consisting of the interchange of helpful suggestions, advice, information, office representation and similar facilities, and in addition a recognition of community of purpose that shall promote in the field of engineering research increasingly intimate relations between engineering and science."

In total, sixty members of the Founder Societies are members of National Research Council, and of these, eight are members of the Foundation Board. The total membership of the National Research Council is about 175. One member of the Engineering Foundation Board and its secretary, and 31 additional members of the Founder Societies, are members of the National Research Council in divisions other than the Division of Engineering and on its Executive Board. Engineers have therefore an influential position in the Council and a large measure of responsibility for its success.

The Engineering Division of the Council has 18 committees, each charged with a specific line of research and together covering a wide variety of subjects of interest to engineers and the industries. It is with this division, as stated before, that the Engineering Foundation is at present most closely associated.

In August 1919 the Executive Committee of the Foundation took action to support preliminary investigations in a number of subjects recommended by the Division.

Research in fatigue phenomena of metals is to be conducted in the laboratories of the Engineering Experiment Station of the University of Illinois under the direction of Prof. H. F. Moore. The Experiment Station shall have the right to publish the results in full as a bulletin of the station, but in addition shall prepare a brief, comprehensive statement suitable for publication in the journals of the engineering societies. A progress report of the Committee on Fatigue Phenomena of Metals, which summarized the facts and theories relating to fatigue failure appeared in the September 1919 issue of MECHANICAL ENGINEERING, p. 731.

From approximately fifty suggestions made to date, the Engineering Foundation Board has selected for investigation six subjects. These are: (1) wear of gears, (2) spray camouflage for ships, (3) directive control of wireless communication, (4) weirs for measurement of water, (5) establishment of a testing station for large water wheels and other large hydraulic equipment, (6) mental hygiene of industry. Investigations 1, 3, 4 and 6 are in progress; the other two have been completed.

An investigation concerning existing industrial research laboratories in the United States has resulted in assembling and classifying some information about each of approximately 250 laboratories connected with the industries, which give whole or part time to industrial research and development. This information is being prepared for publication under the joint auspices of the Engineering Foundation and the Division of Industrial Relations of National Research Council.

# CLASSIFICATION AND COMPENSATION OF ENGINEERS

## Engineering Council Approves Final Report of Committee

IN April 1919 Engineering Council organized a Committee on Classification and Compensation of Engineers, whose object it was to secure better conditions of employment for engineers by classifying engineering positions into several grades, and determining the relative salaries of each. The Committee decided to confine itself to a consideration of engineers engaged in railroad, state, county and municipal, and federal activities and a main committee with three sub-sections was accordingly appointed with chairmen and personnel as follows:

### COMMITTEE ON CLASSIFICATION AND COMPENSATION OF ENGINEERS:

Arthur S. Tuttle, *Chairman*, Deputy Chief Engineer, Board of Estimates and Apportionment, New York, N. Y.  
Francis Lee Stuart, Consulting Engineer, New York, N. Y.  
John C. Hoyt, Chief, Division of Water Resources, U. S. Geological Survey, Washington, D. C.  
Charles Whiting Baker, Consulting Editor, *Engineering News-Record*, New York, N. Y.  
M. O. Leighton, Chairman, National Service Committee of Engineering Council, Washington, D. C.

### Railroad Section:

Francis Lee Stuart, *Chairman*  
Frank H. Clark, Consulting Engineer, New York, N. Y.  
Bion J. Arnold, Consulting Engineer, Chicago, Ill.

### State, County and Municipal Section:

Arthur S. Tuttle, *Chairman*  
M. M. O'Shaughnessy, City Engineer, San Francisco, Cal.  
F. W. Cappellet, City Engineer, Minneapolis, Minn.

### Federal Section:

John C. Hoyt, *Chairman*  
John S. Conway, Asst. Commissioner of Lighthouses, Washington, D. C.  
Oscar C. Merrill, Chief Engineer, Forest Service, Washington, D. C.

From time to time during the year partial and preliminary reports dealing with the work of the sub-committees have been submitted and printed in MECHANICAL ENGINEERING. The main committee has now completed its investigation and submitted its final report to Engineering Council and the complete and definite classification for engineers in federal, state, county and municipal and railroad service was approved by Engineering Council at its meeting on December 18, 1919.

The extracts from this report which follow include a classification of engineers into eight grades, five professional and three sub-professional, and a statement of the necessary qualifications for each; a comparison of the results of this latest investigation with those reported in 1917 by a committee of the American Society of Civil Engineers; and a summary of the returns from the questionnaires, with average ages of incumbents, average salaries in federal, state and municipal service and average salaries recommended by the engineers in charge.

### FINDINGS AND CONCLUSIONS OF THE COMMITTEE

The investigations have shown the lack of any adequate or consistent employment policy with respect to professional engineers. This is evidenced by the following conditions which are believed to be largely responsible for the unsatisfactory status of men engaged in this class of work:

1. Absence of any uniform system of grading of positions
2. Lack of uniformity in titles of positions with respect to duties
3. Inequalities in compensation for positions of the same grade
4. Generally inadequate compensation for services rendered.

To the end that these conditions may be corrected and proper and equitable conditions of employment established, the following principles and practices are recommended by the Committee, though not yet acted upon by Engineering Council.

1. Positions should be classified in accordance with the type of work, and with the character of the duties to be performed and the qualifications necessary for their performance, as indicated by a system of grading.

2. Within the salary limits fixed for each grade, there should be a system of advancement through the grade based upon experience gained in the position and upon proof of increase in the proficiency of the employee in performing the duties of the grade.

3. Promotions from grade to grade should depend upon the existence of a vacancy in the higher grade and proof that the employee is qualified to fill the vacancy.

4. The determination of salary adequate to procure for and retain in engineering work a high class of employees, should take into account and properly weigh the following considerations:

- a. The capital invested, both in money and in time, in obtaining the requisite fundamental training
- b. The amount and character of experience and the degree of personal ability required
- c. The relative value of the classes of work to be performed
- d. The amount paid for similar service in other lines of work
- e. The amount necessary to enable the employee to maintain a standard of living commensurate with the general standards of the community for positions of similar dignity and responsibility.

5. In the interest of an adequate social policy, no position likely to be occupied by individuals of an age to assume family responsibilities should fail to pay an amount sufficient to permit the maintenance of the average family in reasonable decency and comfort.

6. In the interest of the employees as a whole and of the employer, a system should be established by which employees who fail to maintain satisfactory standards of service should be removed, transferred, demoted, or retired as may be equitable in the circumstances.

### CLASSIFICATION OF ENGINEERING POSITIONS IN FEDERAL, STATE, COUNTY, MUNICIPAL AND RAILROAD SERVICES

The grades proposed, which appear to be well adapted to use not only in all of the services represented but also for all other forms of engineering activities, have been divided into two classes, the Professional Service being deemed to include men who have received an engineering degree from an educational institution of recognized standing or who have obtained similar qualifications through practice of the profession and by mastering the fundamentals of engineering science, while the Sub-Professional Service includes assistants with at least a high school education, who enter upon the practice of the profession in the performance of responsible duties for which an engineering training is not essential, but who through experience and study may fit themselves for the higher grades. The classification is as follows:

### PROFESSIONAL SERVICE GRADE 1 CHIEF ENGINEER

**Duties:** To act in chief administrative charge of a technical organization, or of a main division thereof; to determine the general policies of the organization under the limitations imposed by law, regulation, or other fixed requirement; to have final responsibility for the preparation of reports, cost estimates, designs, and specifications and for the construction, maintenance, or operation of engineering works or projects; to have full charge of the collection and presentation of data for and the conduct of valuation proceedings; to conduct or direct the most comprehensive lines of engineering research.

**Qualifications:** Training and experience of a character to give substantial evidence of engineering knowledge and ability or of executive capacity of highest order along lines of work similar to those involved in the position to be occupied and of at least twelve years' duration, of which at least four years shall have been spent in duties of Engineer, or their equivalent, and at least five years in responsible charge of important work or projects. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

## GRADE 2 ENGINEER

**Duties:** Under general administrative direction and within the limits of the general policies of the organization, to have responsible charge of and to initiate and determine policies for a major subdivision of an organization; to prepare for final executive action reports, cost estimates, designs, specifications, and valuation studies and data; to have immediate charge of the construction, maintenance, or operation of engineering works or projects of major importance; to conduct or direct major lines of engineering research; or to furnish for executive action expert or critical advice on engineering works, projects or policies.

**Qualifications:** Active professional practice or executive charge of work for at least eight years, of a character to demonstrate a high degree of initiative and of ability in the administration, design, or construction of engineering work or projects of major importance, of which at least three years shall have been spent in duties of Senior Assistant Engineer, or their equivalent, and at least three years in responsible charge of work. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

## GRADE 3 SENIOR ASSISTANT ENGINEER

**Duties:** Under general administrative and technical direction, to be in responsible charge of an intermediate division of an organization; to exercise independent engineering judgment and assume responsibility in studies and computations necessary for the preparation of reports, cost estimates, designs, specifications, or valuations; to have immediate charge of the construction, maintenance, or operation of important engineering works or projects; or to conduct or direct important lines of engineering research.

**Qualifications:** Active professional practice or executive charge of work for at least five years, of which at least three years shall have been spent in duties of Assistant Engineer, or their equivalent, with at least one year in responsible charge of work. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

## GRADE 4 ASSISTANT ENGINEER

**Duties:** Under specific administrative and technical direction, to be responsible for the conduct of the work of a minor subdivision of an organization; to collect and compile data for specific items of engineering studies; to take immediate charge of field survey projects and of the design and construction of minor engineering work; to lay out and develop work from specifications and to supervise the work of a drafting or computing force; or to conduct specific tests or investigations of apparatus, material, or processes.

**Qualifications:** Experience for at least two years in duties of Junior Assistant Engineer or their equivalent. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

## GRADE 5 JUNIOR ASSISTANT ENGINEER

**Duties:** Under immediate supervision, to perform work involving the use of surveying, measuring, and drafting instruments; to take charge of parties on survey or construction work; to design details from sketches or specifications; to compute and compile data for reports or records; to inspect or investigate minor details of engineering work; or to perform routine tests of apparatus, material, or processes.

**Qualifications:** No experience required other than that involved in securing a professional degree upon the completion of a standard course of engineering instruction in an educational institution of recognized standing; but in absence of such degree, a high school education or its equivalent is required and at least four years' experience in the use of surveying, measuring or drafting instruments, or the computation and compilation of engineering data, together with evidence of a knowledge of the fundamentals of engineering science sufficient, with further experience, to qualify for the higher professional grades. The completion of each full year of such standard course of engineering instruction shall be considered as the equivalent of one year of experience.

## SUB-PROFESSIONAL SERVICE

## GRADE 6 SENIOR AID, OFFICE

**Duties:** To supervise the plotting of notes and maps, and to direct the work of a drafting or computing squad.

**Qualifications:** Experience for at least five years in tracing, lettering, drafting, and computing, of which at least three years shall have

been spent in the duties of draftsman. Education equivalent to graduation from high school. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required, with the provision, however, that at least one year shall have been spent in the duties of draftsman.

## GRADE 6 SENIOR AID, FIELD

**Duties:** To direct work of field party on surveys or construction; to keep survey notes and engineering records; to supervise construction or repair work; to direct the work of computing surveys and estimates; to direct the work of making minor engineering computations.

**Qualifications:** Experience for at least five years in the use and care of surveying instruments, of which at least three years shall have been spent in the duties of instrumentman. Education equivalent to graduation from high school. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required, with the provision, however, that at least one year shall have been spent in the duties of instrumentman.

## GRADE 7 AID, OFFICE

**Duties:** To prepare general working drawings where design is furnished; to plot notes and prepare maps; to design simple structures; to make computations and compile data for reports and records; to check plans, surveys, and other engineering data.

**Qualifications:** Experience for at least two years in tracing, lettering, drafting and computing. Education equivalent to graduation from high school and familiarity with the use of the slide rule, and of logarithmic and other simple mathematical tables. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required.

## GRADE 7 AID, FIELD

**Duties:** To run surveying instruments and to adjust and care for same; to compute surveys and estimates; to make minor engineering computations; to inspect incidentally construction or repair work.

**Qualifications:** Experience for at least two years in the duties of rodman. Education equivalent to graduation from high school and familiarity with the construction, operation, and care of surveying instruments. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required.

## GRADE 8 JUNIOR AID, OFFICE

**Duties:** To trace and letter maps and plans; to make simple drawings from sketches and data; to make minor calculations.

**Qualifications:** Education equivalent to graduation from high school.

## GRADE 8 JUNIOR AID, FIELD

**Duties:** To run tape or leveling rod; to perform other miscellaneous subordinate duties in survey party in field or office, as directed.

**Qualifications:** Education equivalent to graduation from high school.

The completion of each full year of post-graduate work in the specific subject of study or investigation appropriate to a particular service or branch of service shall be considered the equivalent of one and one-half years' general experience, but such substitution shall not thus be made for more than four years of such experience or be considered as reducing the requirements in any grade of the number of years engaged in the conduct or direction of responsible work.

## RESULTS OF INVESTIGATIONS

An analysis of the federal, state, and municipal returns from questionnaires received up to the date of the committee report, December 15, 1919, shows them to be much better than those obtained in the investigation made by the American Society of Civil Engineers in the years 1913-1917. This is due to better cooperation on the part of responsible department heads. The financial status of 10,089 men has now been revealed as compared with a total of 6378 men who replied to the previous inquiry. It also appears that the respondents in the case of the previous investigation were largely confined to the classes receiving a maximum compensation, whereas the present returns cover a much broader range of salary.

Returns from men in federal service representing 16 engineering bureaus in civil establishments and 4 engineering bureaus in the Navy Department, and holding positions of decreasing responsibilities from chief administrative officer having full charge of organization, including determination of policy, to subordinate duty not requiring any special education, training or originality, show a corresponding gradual decrease in average salaries from

approximately \$6000 to \$1000 in civil establishments and from \$10,000 to \$1400 in the Navy Department.

In state service 35 questionnaires from 27 states show a total of 1166 men in professional positions, ages ranging from 21 to 70. The average salary on July 1, 1919, was \$2070 as compared with \$1590 four years previous. This is an increase of 30 per cent, whereas a 72 per cent increase is recommended, making the average salary \$2730. In sub-professional position there is represented 1056 men, ages 18 to 50. The average salary on July 1, 1919, was \$1290 against \$995 in 1915, an increase of 30 per cent. The engineers in charge advocate an average salary of \$1470, a 45 per cent increase.

In municipal service, analysis of 66 questionnaires from 40 cities shows a total of 1478 men in professional positions, ages ranging from 25 to 70. The average salary on July 1, 1919 was \$2370 as compared with \$2230 in 1915, showing an increase of 6.5 per cent. The engineers in charge recommend an average salary of \$3020, which is a 36 per cent increase. In sub-professional positions the returns show 1839 men, ages 17 to 65, average salary 1919, \$1370 against \$1160 in 1915, an increase of 18.5 per cent. The recommendation is for an average salary of \$1700, a 47 per cent increase. It is thus disclosed that the average compensation for grades representing 68 per cent of the engineers in the federal service, other than the War Department, and 80 per cent of those in state and municipal service, is less than is required for the support of a family on a scale sufficient to provide for necessities (assumed at \$2200 per annum), to say nothing of the expense of giving children anything like the education with which the breadwinner was equipped.

It would seem reasonable to assume that men in the "Junior Aid" grade have not reached an age which would require compensation sufficient to support a family, but that the salary limitation for men in higher grades should clearly be sufficient to meet this need. On this basis it is safe to state that with anything like suitable compensation, not more than about 25 per cent of the entire service, if properly organized, should receive less than \$2200 per annum. The investigation made by the State and Municipal Section shows that the average age of the present incumbents of the lowest grades is actually about 27 years; if they are to be adequately provided for as permanent employees, the percentage of men to receive less than \$2200 is clearly negligible.

A comparison with the pay of the industrial worker who serves under the engineer also bears testimony to the fact that, while admitted by none as to value, the actual compensation for brawn is to-day greater than for engineering brain. The need for setting up some scale of compensation for the engineer to correct this serious condition is, therefore, obvious, as is also that for the inquiry now being carried on by the Committee. Unless a radical improvement can be brought about, it seems evident that the profession cannot attract or retain men of the caliber required to command the respect in which it has heretofore been held by the public, and that so long as they are continuously struggling with the problem of making even a bare living, their efficiency will be minimized and their incentive to work with other than a purely selfish interest will be lacking.

That a serious condition of unrest exists in the municipal and state services is clearly evidenced by explicit statements in this respect in 44 per cent of the questionnaires returned, while in only 13 of these services were conditions as to morale reported to be satisfactory.

#### RECOMMENDATIONS

From the investigation made by each of the sections of the Committee, it appears that the heads of sixteen engineering bureaus in the Federal Government (excluding the Navy Department) have recommended an increase in present compensation averaging about 59 per cent, while similar increases in the State and Municipal Services, as recommended by the engineering heads, average 26 per cent.

As a result of the inquiry now in progress under the direction of the Congressional Joint Commission on Reclassification of Salaries, the attention of all members of the federal service has

been drawn to this question in such a way as to make it one of close study and analysis, which condition doubtless accounts for the comparatively modest recommendation made by the representatives of the state and municipal services, whose reply to our inquiry has been individual and who have doubtless been confronted with the necessity of recognizing relationship to other workers in the same services in whose interests no concerted move of this character has been attempted.

The Committee is impressed with the method which has been followed by the Federal Section in setting up a standard of compensation based on a readjustment to the new conditions as to cost of living, this being dependent on an award made on October 24, 1918 by the Shipping Wage Adjustment Board, which was designed to provide uniform national wage scale for all shipbuilding workers, including a scale of compensation for draftsmen and copyists. It is also understood that this wage scale, which is generally known as the Macy Scale, has since been adapted with modifications to the needs of certain bureaus in the Navy Department. In the accompanying diagram there is illustrated a comparison of the compensation fixed under the Macy Scale with the maximum rates suggested by the Federal Section. A further comparison has also been made with scales proposed by other organizations, which seem to justify the schedule of salaries now suggested by the Committee for discussion, which is as follows:

Grade	Total Years Experience Required to Qualify		Salary Range	
	With Professional Degree	Without Professional Degree	Minimum	Maximum
8—Junior Aid		0	\$1080	\$1560
7—Aid		2	1680	2400
6—Senior Aid		5	2520	3240
5—Junior Assistant Engineer	0	4	1620	2580
4—Assistant Engineer	2	6	2700	4140
3—Senior Assistant Engineer	5	9	4320	5760
2—Engineer	8	12	5940	No limit
1—Chief Engineer	12	16	8100	No limit

Applying the average proposed salary to the present incumbents of these positions as reported in the state and municipal services, it will be found that there would be a resulting increase in annual compensation totalling about \$5,500,000 as compared with a total increase of \$2,500,000 recommended by the service heads, against which, however, should be charged the economy growing out of the increased efficiency brought about by a restoration of morale.

The Committee is not prepared at this time to recommend the adoption of any definite schedule of compensation, and it is not at all clear as to the wisdom of fixing even a minimum limit on the highest grades of service or of keeping the maximum of one grade below the minimum of the grade above, all of which questions are now receiving its serious consideration, as is also the question concerning the provision to be made for advancing within the limits of a grade, for which a plan is suggested by the Federal Section. Under this plan it is proposed at yearly intervals, through ratings determined by a Personnel Board, to provide for awarding an increase in compensation to three-fourths of the men in a grade receiving less than the maximum compensation of the grade, who through fitness and industry have shown themselves to be of increased value to the service. Those in the highest third of this preferred list would each receive the maximum rate of increase, which under the proposed scale would be \$480, while each of the next two-thirds would receive an increase of \$240, the latter figure corresponding with what would then be the average increase for all of the men in the grade.

It is also the opinion of the Committee that, pending the completion of the investigation, the scale of compensation presented and the plan for promotion within a grade is adaptable to general use in all branches of engineering service. The Committee believes, however, that a general discussion of this question is desirable.

## CHARLES FREDERIC RAND RETIRES AS PRESIDENT OF THE UNITED ENGINEERING SOCIETY

FOR six years Charles Frederic Rand has been a member of the Board of Trustees of United Engineering Society, the first two as representative of the American Institute of Mining Engineers, and the last four in the presidential chair, and under his able and earnest guidance much has been accomplished. His term of office as president has just expired and upon the occasion of his retirement the Council of The American Society of Mechanical Engineers recognized his services by presenting to him framed resolutions appreciative of his accomplishments. Mr.

has always been to be associated with him personally. I feel very sure, however, that he will always be ready to respond to any call for help which he can give us unofficially.

Mr. Rand is widely known as a mining engineer. He has done considerable work both in this country and abroad, and in 1913 he was decorated by the King of Spain for his notable efforts and accomplishments in advancing the mining industry of that country. Mr. Rand occupies an active and honored position in the affairs of the American Institute of Mining and Metallurgical Engineers and during the year 1913 served as president. He is now one of the directors of the Institute.

During his term of office the activities of the United Engineering Society have greatly expanded. The size of the Engineering Societies Building has been increased by the addition of three stories, two of which are now occupied by the American Society of Civil Engineers. There has thus been brought under one roof the headquarters of the great national engineering societies and this has made for more cooperation along every line.

The Engineering Societies Library has also greatly increased both as to size and the scope of its work. There have likewise been inaugurated two movements of considerable importance to the engineering profession at large. These are the Engineering Foundation for the advancement of research, created by

CHARLES FREDERIC RAND

W. M. McFarland, Mem.Am.Soc.M.E., and one of its representatives on the Board of Trustees of the United Engineering Society, in presenting the resolutions said in part:

It is always a pleasure to find that the faithful and efficient performance of duty has been appreciated by those for whose benefit it has been done, and it is a still greater pleasure when this appreciation is accompanied by its definite expression at a time when it will be a satisfaction and a slight reward to the one whose actions are commended.

With the realization of the fact that with this meeting the service of our esteemed associate, Mr. Charles F. Rand, as President of the United Engineering Society comes to a close by the termination of his service as a member, the representatives of The American Society of Mechanical Engineers brought this fact to the attention of the Council of that Society and took occasion to praise the devotion to the interests of united engineering which had been shown by Mr. Rand, first as Chairman of the Finance Committee and later as President.

The Council thereupon passed a suitable resolution expressive of their appreciation of Mr. Rand's work and directed that it be suitably engrossed and presented to him.

The pleasant duty of presenting these resolutions to Mr. Rand has been delegated to me, and it gives me very great pleasure to transmit to him this expression of the appreciation by one of the great American engineering societies for the splendid work which he has done in advancing the united interests of the engineers of America.

I feel that I am not only voicing my own sentiments but those of the entire Board when I express the deepest regret that the termination of his services will deprive us of the benefit officially of his ability, tact and wise judgment in the administration of the affairs of United Engineering Society, and of the great pleasure which it

### THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

tenders its greetings to

THE UNITED ENGINEERING SOCIETY

and desires to record its appreciation of the services rendered to the Engineering Profession by

CHARLES FREDERIC RAND

President, United Engineering Society

WHO through his devotion to the highest ideals was by his tact and good judgment, enabled to bring about that degree of co-operation among the Engineering Societies of the United States which may be characterized as the beginning of our professional unity. This was made possible the fulfillment of the dream of Andrew Carnegie who, with his appreciation of the services of engineers in helping him to achieve his eminence in this iron age, visioned even greater achievements for civilization by union of effort, and sought to bring it about by his Deed of Gift which resulted in the organization of The United Engineering Society and the realization of this splendid building, which has become the national headquarters for the engineering profession in America

HONOR CUI HONOR DEBETUR

By the Council of The American Society of Mechanical Engineers on regular session, December 31st, Nineteen Hundred and Nineteen

*Edw. G. Swasey*  
By the Council  
*Edw. G. Swasey*  
Secretary

a gift of \$200,000 from Mr. Ambrose Swasey, and Engineering Council, an organization devoted to a consideration of matters pertaining more particularly to the engineer's relation to public welfare. Both of these organizations have contributed largely toward the advancement of the engineering profession, and Mr. Rand's participation in their activities has always been helpful and sympathetic.

# LIBRARY NOTES AND BOOK REVIEWS

## United Engineering Societies Library Issues Annual Report

The Library Board of the United Engineering Societies Library, which collection embraces the libraries of the American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Institute of Mining Engineers, has just issued its annual report for 1919.

The officers of the Board for the year 1919 were E. Gybbon Spilsbury, Chairman, Samuel Sheldon, Vice-Chairman, and Harrison W. Craver, Secretary. The four societies were represented on the Board as follows:

### AMERICAN SOCIETY OF CIVIL ENGINEERS

Alfred D. Flinn                      Arthur P. Davis  
John A. O'Connor                  Willard Redman  
Charles Warren Hunt

### AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Jesse M. Smith                      William N. Best  
Walter M. McFarland              L. P. Brockbridge<sup>2</sup>  
Andrew M. Hunt                    Calvin W. Rice

### AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS

E. Gybbon Spilsbury              Alex. C. Humphreys  
George C. Stone                    John H. Janeway  
Bradley Stoughton

### AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

Samuel Sheldon                    W. I. Slichter  
Edward D. Adams                  A. W. Kiddle  
F. L. Hutchinson

The year has been marked by an increased use of the Library in every direction. The number of readers during 1919 was 22,042, an increase of 6979, or 46 per cent over 1918. The attendance after six in the evening was 15 per cent of this, or 3470. The average daily attendance was 72.

Over 2000 telephone inquiries were received during the year and approximately 1500 letters which did not require elaborate investigation were received and answered. In other words, over 3500 persons not represented in the attendance figures nor in the records of the Service Bureau have been helped by the Library.

As in previous years, the Service Bureau has cared for the work requiring extended research, the preparation of translations, and copies of articles and bibliographies. During the year 552 searches, chiefly bibliographic, were prepared in answer to specific inquiries. Of these, the classification of searches by branches of engineering shows the largest number to have been made in the field of mechanical engineering; mining and metallurgical engineering ranking second. Some of these bibliographies were of great extent, requiring the time of one or two people for weeks and even months; and the work done exceeded that in 1918 by an amount greater than the increase of 44 in the number of searches indicates. The number of translations made was 71, containing 227,300 words. In 1918 there were 78 translations, amounting to 258,080 words. The orders for photographic copies of articles amounted to 2319 and required 23,951 prints. In 1918 there were 1150 orders for 6306 prints. This increase of 101 per cent in orders shows the wide appreciation of this form of assistance, which appeals particularly to those far from libraries. Copies have been made for engineers in every continent.

The resources of the Library, on January 1, 1919, were:

	Volumes	Pamphlets	Total
Accessioned material	104,858	31,034	135,892
Unaccessioned material	13,062	7,941	21,003
Total	118,820	38,975	157,795

By December 31, 1919, all unaccessioned material had been examined and either accessioned or placed among duplicates. At that date the permanent collection contained a total of 152,091

volumes, pamphlets, maps and plans, and searches. There were also on hand 3958 duplicate volumes and 2076 duplicate pamphlets.

The receipts during the year were:

	Gift	Purchase	Total
Volumes	2,384	553	2,937
Pamphlets	3,205	232	3,437
Maps and plans	118	...	118
Searches	...	...	501
	5,707	785	6,093

As in former years, the Library has received considerable important material by gift. The majority of the technical publications of American publishers have been sent for review in the publications of the Founder Societies, and there have also been many valuable gifts from individuals.

The technical work of the Library during the past year consisted principally in recataloging. A complete report of this work has been prepared by Harrison W. Craver, Director of the Library, and was published in the September 1919 number of MECHANICAL ENGINEERING, page 782. Arrangements for the work were made in May, and Miss Margaret Mann, formerly Chief Cataloger of the Carnegie Library of Pittsburgh, was engaged as cataloger. The work was begun on July 1, since which time the cataloging of new accessions and the recataloging of old material have proceeded simultaneously.

At the end of the year all unaccessioned material had been examined and either cataloged, listed as duplicates or discarded as valueless. The number of volumes completely cataloged was 6671, while 2210 duplicates had been listed, 374 searches had been cataloged and 1612 volumes added to the records as additions to existing sets. An index to the new catalog, containing 2920 entries, had been compiled and 6899 cards had been added to the catalog. The speed of the department has increased at a rapid rate as preliminary points have been settled and methods of procedure determined. The total work of the catalog department during the year, including that prior to the reorganization of the department, was 3009 volumes, pamphlets, maps and plans, and searches cataloged, and 5984 recataloged, totaling 8993. These figures, while they express the net results, are by no means an accurate index of the amount of work done. Much time is spent in collecting sets from their various locations, in correcting inaccurate records and in collating sets of periodicals and Government publications.

Changes in the staff have been less frequent than in previous years, and the effect of experience has been favorably shown in more helpful service.

The new system of cataloging the Library substitutes for all the old catalogs an author catalog and a classed subject catalog, the latter to be accompanied by a very full index. A classed subject catalog enters a book in that place in the catalog where all similar entries on the subject are collected. The author catalog will enable the reader to find a book when the name of the author is known, to find what books by any author are in the library, and also the various editions available; translations as well as their originals will be shown. The subject catalog will enable the reader to find a book when the subject is known, and will exhibit the resources of the Library in orderly form on every chief and most subordinate topics within its chosen field. The alphabetical index will comprise the names of the subjects of knowledge upon which the Library possesses important books or pamphlets, and it will at once direct the user to that section of the subject catalog where these books are listed and to the department of the Library where these works are shelved. When these catalogs are completed the catalog equipment of the Engineering Societies Library will be as complete, detailed and satisfactory as it is possible to make it, as well as a true and helpful guide for all reasonable methods of approach by readers.

<sup>1</sup> Resigned May, 1919.

## BOOK REVIEWS

**L'ALUMINUM DANS L'INDUSTRIE.** Métal pur Alliages D'Aluminium. By Jean Escard. H. Dunod et E. Pinat, Paris, 1918. Cloth, 6 x 10 in., 272 pp., illus., 18 francs.

The subjects discussed include the manufacture of aluminum, its physical and chemical properties, soldering, the influence of mechanical treatment on its properties, and its applications in metallurgy, electrical and mechanical industries, etc. The constitution, properties and uses of the various aluminum bronzes and alloys of aluminum with various metals, both common and rare, are described, and a final chapter treats of alloys with silicon, aluminum carbides and nitrides, and several alloys for special purposes. The volume gives a concise survey of present knowledge of aluminum.

**APPLIED SCIENCE FOR METAL WORKERS.** APPLIED SCIENCE FOR WOODWORKERS. By William H. Dooley. The Ronald Press Co., New York, 1919, \$2 each.

These volumes present a course in the general principles of science, which gives particular attention to their applications in industry and is intended for use in vocational high schools, industrial schools, apprentice classes, etc. The general scientific matter in the two books is identical. Additional material relating specifically to the woodworking trades appears in one, while the other treats of metal-working in similar fashion.

**BUILDING OF THE PACIFIC RAILWAY.** The Construction-Story of America's First Iron Thoroughfare between the Missouri River and California. From the Inception of the Great Idea to the Day, May 10, 1869, when the Union Pacific and the Central Pacific joined tracks at Promontory Point, Utah, to form the Nation's Transcontinental. By Edwin L. Sabin. J. B. Lippincott Co., Philadelphia, 1919. Cloth, 5 x 8 in., 317 pp., 10 pl., 4 portraits, 1 map, \$2.

Mr. Sabin's object has been to tell how the Pacific railway came into being; to describe the actual building operations by which the Union Pacific Railroad, from the Missouri River, and the Central Pacific Railroad, from the Sacramento River, were constructed in six years instead of the allotted fourteen. The book is a popular, readable account of the men who built the roads and of the methods used.

**CLAY-PLANT CONSTRUCTION AND OPERATION.** By A. F. Greaves-Walker. Brick and Clay Record, Chicago, 1919. Cloth, 6 x 9 in., 212 pp., 79 illus., \$4.

In writing this work the author has attempted to explain in understandable English some of the problems of the manufacturer of structural clay products. Technical terms, formulae, and theories have been avoided, and practical facts alone have been presented.

**ELECTRICAL ENGINEERING PAPERS.** By Benjamin G. Lamme. This volume contains a collection of the author's most important engineering papers presented before various technical societies and published in engineering journals and elsewhere from time to time, 1919. Published by Westinghouse Electric & Mfg. Co., Pittsburgh, Pa. Cloth, 6 x 9 in., 773 pp., illus., \$2.50.

A collection of thirty-one papers and addresses which have appeared in various periodicals during the period from 1897 to 1918. These papers deal with problems of generator and motor design, the history of direct-current generators and of street-railway motors, and with technical training. The volume is published by the Westinghouse Electric and Manufacturing Company to commemorate Mr. Lamme's connection with it for thirty years.

**ELEMENTARY PRINCIPLES OF AIRPLANE DESIGN AND CONSTRUCTION.** A Textbook for Students, Draughtsmen, and Engineers. By Arthur W. Judge, James Selwyn and Co. Ltd., New York, 1919. Cloth, 6 x 9 in., 116 pp., 56 illus., 13 tables, \$3.

Written to provide an inexpensive book, of an elementary nature, dealing with the fundamental principles of the design and, to a certain extent, the construction of airplanes. Follows the plan of the author's larger work, to which it may serve as an introduction.

**FUNDAMENTALS OF CONTINUOUS CURRENTS OF ELECTRICITY.** Book II of text-book series, School of Practical Electricity. By O. Werwath, assisted by Messrs. Vaughn, Hughes and Raeth. Electroforce Publishing Co., Milwaukee, Wis. 133 pp., illus., tables.

This book covers the fundamental principles of continuous current or direct electric current. It contains a nomenclature of electrical terms, discussion of Motric methods, basic electrical units, mechanical and electrical work and energy and detailed chapters on types of electrical circuits, electricity meters, resistance measurements, and electrical heating.

**GUIDE TO THE STUDY OF THE IONIC VALVE.** Showing its Development and Application to Wireless Telegraphy and Telephony. By William D. Owen. Sir Isaac Pitman and Sons, London. Cloth, 4 x 6 in., 50 pp., 12 illus., \$1.

This little volume is intended to provide, for students of radio-telegraphy, an impartial, coherent record of the development of the ionic valve. References to the original sources of the information enable the reader to pursue his study of the subject.

**INDUSTRIAL RECONSTRUCTION PROBLEMS.** Complete Report of the Proceedings of the National Engineers. New York City, March 18-24, 1919. Paper, 6 x 9 in., 197 pp.

The papers presented at the conference dealt with a wide variety of problems connected with the reorganization of our industries on a peace basis. Consideration is given to questions of finance, commerce, production, labor, education, management, etc.

**MACHINE TOOL OPERATION.** Part I. The Lathe Bench Work and Work at the Forge. By Henry D. Burghardt. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 5 x 8 in., 326 pp., illus., tables, \$2.

The author of this work has used his experience as a teacher of machine work in a technical high school to prepare a text-book for those who desire a knowledge of the principles and elementary operations of machine-shop work, suitable for use in technical and trade schools and in apprenticeship courses. While designed primarily for use in connection with lectures by an instructor, it is also useful for self instruction.

**THE MANUFACTURE AND TESTING OF MILITARY EXPLOSIVES.** By John Albert Marshall. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 8 in., 261 pp., \$3.

This volume contains a concise account of the explosives used for military purposes, in which attention is directed to those points which have a direct bearing on their manufacture, testing and storage. An extensive bibliography is included.

**METAL WORKER'S HANDBOOK OF RECEIPTS AND PROCESSES.** Being a collection of chemical formulas and practical manipulations for the working of all the metals and alloys; including the decoration and beautifying of articles manufactured therefrom, as well as their preservation. Edited by William T. Brannet. New enlarged edition. Henry Carey Baird and Co., Inc., New York, 1919. Cloth, 5 x 8 in., 582 pp., illus., tables, \$3.

Five new chapters have been added to the present edition of this work, describing methods for welding with the oxy-acetylene flame, thermit and electricity, for galvanizing and for die casting.

**MILLIONS FROM WASTE.** By Frederick A. Talbot. J. B. Lippincott Co., Philadelphia, 1920. Cloth, 6 x 9 in., 308 pp., \$5.

This work is written to indicate certain of the most obvious channels through which wealth incalculable is being permitted to escape, as well to describe some of the highly ingenious efforts which are being made to prevent this wastage. While written essentially for the uninitiated, it will, the author hopes, prove of aid to those who are fully alive to the potential values of refuse. The volume is confined to those phases of the subject which are familiar to the average person.

**MINERAL DEPOSITS.** By Waldemar Lindgren. Second Edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 957 pp., illus., tables, \$5.

Mineral deposits are usually classified and described by the metals or substances which they contain; for instance, deposits of copper are described together, with little or no effort to separate them into genetic groups. This book is the outcome of a desire to place the knowledge of mineral deposits on the broader and more comprehensive basis of a consistent genetic classification and thus bring it into a more worthy position as an important branch of geology.

In this second edition, all of the chapters have been revised and several have been largely rewritten. A discussion of metallogenic epochs has been added, as well as an index by elements. Some less essential descriptions have been excised in order that the book might not increase in bulk.

**OIL ENGINES.** Details and Operation. By Lacey H. Morrison. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 472 pp., illus., tables, diagrams, 85.

This volume is intended for operators of oil engines. The details of construction of the more important oil engines manufactured in the United States are described and the proper methods of adjustment are explained at length.

**THE PETROLEUM HANDBOOK.** By Stephen O. Andros. The Shaw Publishing Co., Chicago, 1919. Flexible cloth, 4 x 7 in., 206 pp., illus., tables, 82.

In a book of pocket size, the author gives the fundamentals of each phase of the oil industry necessary to a clear understanding of the various operations entailed between the location of an oil well and the distribution of the refined products. The work is chiefly a compilation from the standard authorities, arranged for those who wish a brief, accurate account of the industry, devoid of unnecessary detail.

**PRINCIPLES OF INDUSTRIAL ORGANIZATION.** By Dexter S. Kimball. Second edition, revised and enlarged. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 325 pp., 21 illus., 12 tables, 83.

This work, the first edition of which appeared in 1913, has been written to give young engineers a concise account of the salient facts regarding the most important economic and sociological problems with which they will be brought in contact, and to explain the origin and growth of the important features of industrial organization. The present edition has been revised, rearranged and enlarged.

**PRINCIPLES OF REINFORCED CONCRETE CONSTRUCTION.** By F. E. Turneaure and E. K. Maurer. Third edition, revised and enlarged. John Wiley and Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 485 pp., illus., diag., pl., tables.

Like former editions, this work is intended "to present in a systematic manner those principles in mechanics underlying the design of reinforced concrete; to present the results of all available tests that will aid in establishing coefficients in working stresses; and to give such illustrative material from actual designs as will serve to make clear the principles involved." In the present edition the material has been considerably amplified and rearranged. Separate chapters have been devoted to the theory of flexure; bond and shear; and the design of beams. The experimental data have been reviewed. A new chapter on flat slabs has been added and the chapter on building construction extended.

**RETAINING WALLS.**—Based entirely on the Theory of Friction. By Pedro Dozal. Translated into English by R. T. Muleddy. First edition. M. A. Rosas, Buenos Aires, 1918. Cloth, 7 x 11 in., 161 pp., 62 illus.

The author presents a general theory in regard to the static pressures acting on a plane cutting an unbounded coherent, incoherent or liquid mass in equilibrium, and its application for the calculation of the pressures on retaining walls. The theory advanced differs from those presented by Rankine and other students of the subject and gives notably different results.

**SCHOOL OF PRACTICAL ELECTRICITY.** Book I of text-book series. By Oscar W. Wadsworth. Electroforce Publishing Co., Milwaukee, Wis., 1919. 60 pp., illus.

This practical text book, written by the president of the School of Engineering of Milwaukee in collaboration with several members of his faculty, sets forth the advanced methods of electrical instruction as taught at the School in a clear-cut, expository form, avoiding dry technicalities. It includes the history of electricity, detailed treatment of the telephone and telegraph systems, definitions of electrical terms, practical estimates and pointers regard-

ing electrical workmanship and installations of all kinds, and experimental outlines for the electrical laboratory.

**SELENIUM CELLS.** The Construction, Care and Use of Selenium Cells with special reference to the Fritts Cell. By Thomas V. Benson. Spon and Chamberlain, New York, 1919. Cloth, 5 x 8 in., 63 pp., 18 illus., \$1.50.

The lack of definite information on the construction of selenium cells has led the author to publish the results of some of his experiments. After a brief review of various types of cells, the book describes in detail the manufacture, maturing and testing of the Fritts cell, and concludes with an account of some applications and suggestions on the care of cells.

**TIMBER. ITS STRENGTH, SEASONING AND GRADING.** By Harold S. Betts. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 234 pp., illus., maps, charts, tables, 88.

This volume, for engineers, manufacturers and users of lumber and wood material, is intended to meet the lack of a work on wood as a structural material, similar to existing handbooks on steel, concrete, etc. The methods of testing the strength of wood and wood products, such as telephone poles, packing boxes and vehicle parts, are described and the results of numerous tests by the Forest Service are tabulated. A table based on 130,000 tests, showing the average mechanical properties of 124 American woods, is given. Proper methods of seasoning wood are fully discussed. The grading rules of the different manufacturers' associations are given and the book closes with extensive statistics on the lumber produced and used in the United States.

## MECHANICAL ENGINEERING LABORATORY, UNIVERSITY OF ILLINOIS

(Continued from page 113)

supplying the laboratory or from the exhausts from the ammonia and brine pumps. A 24-in. by 12-ft. generator is installed for this purpose. A 10-in. by 19-in. brine cooler is placed on the lower floor, and is arranged so that the brine may be circulated either through the reheater or the brine tank.

Both machines are completely equipped with thermometer wells and weighing tanks, and are especially arranged for accessibility.

### INTERNAL-COMBUSTION ENGINES AND GAS PRODUCER

The section of the laboratory devoted to internal-combustion engines and the gas producer is located at the west end of the middle bay. At the extreme west of this bay is located a Smith gas producer rated at 75 hp. capacity. The producer (34) is complete with a gas-cleaning plant and is designed to operate continuously on bituminous coals.

In the opposite corner of the same bay with the gas producer there is to be installed an automobile-testing plant. This plant will be designed so as to be suitable for the testing of all sizes of pleasure cars and trucks up to five tons capacity. It is intended to measure the drawbar pull directly, and it will be possible to make various kinds of comparative tests on motor vehicle parts with this outfit.

While the automobile-testing plant is not yet installed, the laboratory has facilities to carry on tests of automobile, truck, tractor and even airplane motors. The principal unit of this equipment is a complete Sprague electric dynamometer (32a) of 150 hp. capacity. This outfit can be used either as an absorption or as a transmission dynamometer. At present a 4-cylinder Willys-Knight motor, a 4-cylinder Ford and a Peerless 6-cylinder motor (31) comprise the engine equipment for running tests with the dynamometer. A water brake designed by Dean C. R. Richards and built in the Mechanical Engineering Shops of the University of Illinois is shown in the plan view connected to the 6-cylinder 70-hp. Peerless motor (31).

The first large unit in the stationary gas-engine equipment is a single-acting, four-cycle horizontal 10-in. by 19-in. Otto engine rated at 25 hp. at 220 r.p.m., piped to the gas producer and supplied with the gas from the producer when desired.

There is also installed a smaller Otto single-acting, four-cycle 5 1/2-in. by 12 1/2-in. gas or gasoline engine (29) rated at 10 hp. at 240 r.p.m.; a 9-in. by 9-in. single-acting four-cycle Bogart engine (28), which is rated at 10 hp. when running at 315 r.p.m., and may be operated on either illuminating gas or gasoline; a Mietz and Weiss single-acting 9-in. by 10-in. engine (27), rated at 12 hp. at 240 r.p.m., and using kerosene as fuel with a hot-bulb type of ignition; and a Sargent 10-in. by 20-in. tandem double-acting four-cycle "complete expansion" engine (24), rated at 50 hp. at 250 r.p.m. and using illuminating gas for fuel. Mr. Sargent, the designer and inventor of this engine, is an alumnus of the College of Engineering, University of Illinois.

## The First Transcontinental Motor Convoy

An Account of the Successful Attempt Made by the War Department to Push Through a Large Train of Heavily Loaded Motor Trucks from Washington, D.C., to San Francisco, Together with Particulars of the Itinerary, Personnel, Operation and Maintenance Problems, and Conclusions Reached

By E. R. JACKSON, WASHINGTON, D. C.

THE Transcontinental Motor Convoy which started from Camp Meigs, Washington, D. C., at 8 a. m. on July 7, 1919, and finished at San Francisco, Cal., on September 6, 1919, was the first attempt to push through a large train of heavily loaded trucks from one end of the country to the other. Back of it were placed the resources of the War Department, and some measure of its success was due to the friendly co-operation of the local bodies of the communities through which the Convoy passed.

### OBJECTS OF THE TRIP

The four purposes of the trip were as follows:

- 1 The War Department's contribution to the Good Roads movement for the purpose of encouraging the construction of through-route and transcontinental highways as a military and economic asset.
- 2 The procurement of recruits for the enlisted personnel of the Motor Transport Corps, or any other branch of the U. S. Army, young men to be enlisted with the train as candidates for

The writer was acting as Ordnance Observer for the Chief of Ordnance, attached to the Transcontinental Motor Convoy, and accompanied this truck train the entire distance from Washington, D. C., to San Francisco.

The Convoy departed from Camp Meigs at 8:30 Monday morning, July 7, 1919, proceeding to the Ellipse in Potomac Park, opposite the south front of the White House, where the Zero Milestone was dedicated by the National Highways Association in the presence of the Secretary of War, the Chief of Staff, general officers of the Army, and several Senators and Congressmen. Following his acceptance of the Zero Milestone on behalf of the President of the United States, Secretary Baker formally directed the Convoy to proceed overland to San Francisco, Cal., via the Lincoln Highway.

### ITINERARY

Several days before it started the Convoy received from the Motor Transport Corps an itinerary giving scheduled control points, mileage and dates of arrival. Orders were given by the Secretary of War and Brig.-Gen. C. B. Drake of the Motor

FIG. 1 ROUTE OF THE FIRST TRANSCONTINENTAL MOTOR CONVOY—CAMP MEIGS, WASHINGTON, D.C., TO SAN FRANCISCO, CAL., JULY 7, TO SEPT. 6, 1919

the mechanical training schools opened under the direction of the Motor Transport Corps.

3 An exhibition to the general public, either through actual contact or resulting channels of publicity of the development of the motor vehicle for military purposes, which is conceded to be one of the principal factors contributing to the winning of the World War.

4 An extensive study and observation of terrain and standard army motor vehicles by certain branches of the army, particularly the Field Artillery, the Coast Artillery, the Air Service, the Corps of Engineers, and the Ordnance Department.

<sup>1</sup> Former 1st Lieut., Ord. Dept., U. S. A. Ordnance Observer.

For presentation at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

Transport Corps, to hold to the schedule as closely as possible, and it is noteworthy that the Convoy arrived at Lexington, Neb., almost exactly half-way across the continent, on August 1 on time, thanks to the good roads of Pennsylvania, Ohio, Indiana and Illinois and to the fact that the gumbo roads of Iowa were dry and hard, there having been no rain in that state for several weeks previous to the arrival of the Convoy.

From this point west and until the Convoy reached the palm-lined boulevards of California the roads grew steadily worse except in the vicinity of Salt Lake City, Utah, and it became increasingly difficult to get the heaviest trucks through the soft, muddy roads and over the bad grades. The greater part of the Convoy trucks could not have reached San Francisco without the assistance rendered by the Miltor and the 5-ton artillery tractor, produced by the Ordnance Department.

## PERSONNEL

The personnel of the Convoy consisted of Companies E and F of the 433d Motor Supply Train, comprised of 12 officers and 210 men; Service Park Unit No. 595, 1 officer and 38 men; Company E, 5th Engineers, 2 officers and 30 men; 1 Medical Detachment; 1 Field Artillery Detachment; and 17 commissioned officers detailed to duty as staff observers.

The majority of the enlisted men of the Motor Supply Train were raw recruits with little or no military training, many of whom had not driven a motor truck before. Considering this fact, the success of the Convoy is quite remarkable, as the roads encountered through the mountains of the West required driving skill of the highest order. The men were poorly equipped at the start, due to the fact that many of them joined at the very last minute.

FIG. 2 ARTILLERY TRACTOR USED TO PULL BIG TRUCKS OUT OF BAD SPOTS. REPAIRING A BROKEN TRACK LINE

FIG. 3 CLASS B TRUCKS, CHAINED TOGETHER, MAKING GRADE AFTER FIRST ONE HAD BEEN TOWED OVER TOP BY TRACTOR. EAST OF BIG SPRINGS, NEB., AUG. 6, 1919

The other units were better trained and better equipped. The Engineer Corps and the Medical Detachment were especially efficient organizations. Much credit should be given to the Engineers for the extremely valuable work which they did in repairing roads and bridges, without which the expedition must have failed. The Medical Detachment handled all matters of camp sanitation and precautionary measures in a most satisfactory manner and as a result practically the entire personnel enjoyed excellent health during the whole trip.

## OPERATIONS

The Convoy was made up of 81 motor vehicles and trailers.

The performance of the various types of motor equipment is one of the chief points of interest to the engineering fraternity, inasmuch as it affords a most excellent opportunity for making valuable comparisons as to the ability and reliability of the several makes of motor vehicles and trailers. Practically all of the equipment was new when the Convoy left Washington, the exceptions being the Militor (the standardized four-wheel-drive motor vehicle of the U. S. Army) and the 5-ton artillery tractor, both of which were designed and built by the Ordnance Department, so that in so far as the condition of the vehicles was concerned, all had an equal chance of successfully completing the long journey across the continent.

While the cargoes carried varied somewhat from day to day, it may be said that in general the trucks hauled capacity loads. The most uncertain factor in the operation of these motor vehicles, especially during the first few weeks of the trip, was the

FIG. 4 TRUCK STUCK IN MUD SO BADLY THAT A 1 1/2-IN. MANILA ROPE AROUND WINCH OF MILITOR BROKE

FIG. 5 MACK TRUCK BREAKING THROUGH SMALL WOODEN BRIDGE, 31 MILES WEST OF GREEN RIVER, WYO., AUG. 15, 1919

inexperience of the drivers, all of whom were new to convoy work. Even during the first half of the trip, where the roads were generally good, some drivers had considerable difficulty in keeping their trucks on the road. After the train officers had had ample opportunity to observe the comparative ability of the men for a few weeks, the best drivers were each assigned to one of the motor vehicles with an assistant driver and made fully responsible for the operation of their equipment. Immediately upon arrival at the control point for the night it was the duty of the driver to see that his truck was at once filled with gasoline, oil and water, cleaned, and any needed adjustments or repairs made. Three officers of the Motor Transport Corps inspected each vehicle every morning before the Convoy left camp, to see that

this work had been properly done. This resulted in a very marked lessening of mechanical troubles on the road and a much more efficient operation of the entire equipment. As the Convoy proceeded across the country the men gained experience with their trucks and confidence in themselves, so that by the time the mountains and deserts were reached most of them were equal to the difficult tasks encountered there, and when the train reached San Francisco many of the men were really competent drivers, and their development as such is deserving of favorable comment. It is a truly noteworthy achievement that there were no trucks lost on the very dangerous mountain grades of the Rockies and Sierras.

Excellent work was done by the two pilots, who left camp on motoreycles each morning about one-half hour in advance of the

# MAINTENANCE

The maintenance and repair of the Convoy vehicles was the principal function of Service Park Unit No. 595, and the fact that only three trucks were retired from service en route bears tribute to the effectiveness with which they did their work. Included in this detachment were expert mechanics on motoreycles, motors, carburetors, magnetos, radiators, and tires, machinists, painters, welders, blacksmiths, and carpenters; each man a specialist in his own line of work. These men did very excellent work in general, frequently working all night in order to have some truck ready to run under its own power when the Convoy broke camp in the morning, and some very clever repairs were made with the facilities available. New connecting-rod bearings were fitted frequently, damaged cylinder blocks replaced, cracked

Convoy to see that the road was clear and to report any obstructions or deviations to the expeditionary commander. The simple road-marking system used by the pilots proved to be a great success. The markers consisted of salmon-colored paper isosceles right-angle triangles which were tacked on a conspicuous post or fence at each turn of the road or intersection. When the apex of the triangle pointed up it indicated that the route was straight ahead; apex pointing to the right indicated right turn; apex pointing left, left turn; and two triangles tacked up base to base, thus forming a square, indicated the location of the camp site. Without these markers considerable difficulty would have been experienced in following the route through cities, on detour. In the absence of official Lincoln Highway markers, or where those were interspersed with other highway markers.

crankcases repaired, new clutch assemblies installed, and even babbitt bearings poured on the roadside very satisfactorily.

The maintenance work was considerably hampered because of the necessity of carrying spare parts for so many different makes of trucks and the additional fact that the stock carried had not been intelligently selected. Large stocks of such parts as axles and drive shafts, among which there were no breakages, were carried, while no spares whatever were taken of many other parts, including radiators, on which there were frequent failures. In a few instances it was possible to replace a broken or worn part in one truck with a spare part for another make of truck, when careful calibration showed the dimensions to be practically the same. Another difficulty was due to the poor quality of the hand tools supplied, and better tools should be furnished the

mechanics, as well as such special tools as are necessary to make certain adjustments properly.

#### GENERAL CONCLUSIONS

In general, very few serious automotive troubles developed, but the experience gained on the trip and the information secured from an examination of each vehicle after arrival at San Francisco would seem to warrant the following statements:

**Cooling Systems.** The vertical tubular type of radiator, with bolted-on upper and lower tanks, is the most satisfactory on military vehicles, because of the facility with which it may be cleaned and repaired. The addition of a temperature regulator in the water line, which would restrict the flow of water until the motor had warmed up and such as is now standard equipment on many commercial trucks, would be most desirable. Such a device would be simpler and less expensive to install than radiator shutters, less liable to damage, and is automatic in its operation.

An endless flat fan belt, of leather or rubberized fabric, is most desirable for military motor vehicles, and an effort should be made to standardize the width and length of these belts. An extra endless belt should be carried in each vehicle at all times. The

The present acetylene headlights used on all trucks are entirely inadequate, and the carbide generators are unsatisfactory and poorly constructed. It is believed that an efficient system of electrical lighting should be adopted for all military trucks. Such a system was developed for the Ordnance Department during the war by Mr. R. M. Newbold and found satisfactory.

The use of mechanical or electrical self-starters on military vehicles is undesirable, as they merely add complications to the operation and maintenance of the trucks.

All service cars should be equipped with four electric spotlights for night repair work.

**Fuel Systems.** Except for a few broken gasoline lines the fuel systems now in use are generally satisfactory, although larger drain cocks in all gasoline tanks would be desirable.

**Transmission Systems.** A driving worm of 24 pitch instead of 33½ pitch is recommended for all Class B trucks. Of the three Class B tankers, the one with the 33½-pitch worm was the one which was most frequently stalled.

It is recommended that steps be taken to have all future military motorcycles equipped with a complete protective guard around the drive-chain system. Some steps should also be taken

FIG. 10 CLASS B TRUCK, TOWING TWO-WHEEL LIBERTY KITCHEN TRAILER, STUCK ON SANDY GRADE, AND TOWED OVER BY TRACTOR

FIG. 11 ORDNANCE-BUILT TRACTOR PULLING HEAVY TRUCKS OUT OF MUD NEAR GOTHENBURG, NEB., AUG. 3, 1919

"V" fan belts are not desirable, but if used, some form of a dust pan should be placed in front of the lower fan-belt pulley to protect the "V" belt.

**Motors.** Because of the high percentage of failures experienced with certain valve-tappet rollers and guides and the valve springs, prompt attention should be paid to the development of a more durable valve-lifter assembly, which will be interchangeable with that now in use. It is suggested that steel be used in the construction of the guide instead of cast iron, as at present, and that the valve springs be heat-treated more carefully.

The governors of all trucks in the Convoy were rendered useless during the first few days of the trip, resulting later in many burned-out connecting-rod bearings, due to speeding the vehicles. Some means should be provided to protect the governors against tampering on the part of drivers and mechanics.

A simplified carburetor would be advantageous on cars having sensitive automatic throttle and auxiliary air valve, as these are not thoroughly understood by the average mechanic.

Only the very best grades of oil should be used in motors, and a simple and positive means of determining the oil level should be provided on every truck.

A study should be made of the conditions which are responsible for the blowing out of cylinder-head gaskets in the motor of the Standardized Class B trucks, and such changes made as may be necessary to eliminate this trouble.

The mufflers on some of the trucks were found to clog up easily and this matter should be given careful attention.

**Ignition and Electrical Systems.** The Bosch magneto used on the Standardized Class B truck should be corrected to have a greater air gap between the pencil and the distributor block.

to provide for a unit power plant, eliminating the short drive chain. In future development steps should be taken to eliminate the chain drive entirely and to substitute shaft drive. There are no insurmountable difficulties to the inclusion of this type of drive in a motorcycle, but it cannot, however, be applied when the V-type two-cylinder motorcycle motor is used.

Chain-driven trucks cannot be operated satisfactorily where soft, sandy or muddy roads are encountered. They are essentially good-roads trucks.

As an automotive principle the four-wheel drive was surely vindicated by the Militor and the F. W. D. trucks. It is believed that the Militor is the most powerful wheeled motor vehicle constructed up to the present time.

**Vehicle Controls.** The steering gears gave very little trouble, but better lubricating facilities are desirable to secure the ease of steering which is so necessary on a motor truck, especially when operating on heavy roads, as some types are very hard to operate on rough roads.

On one class of trucks the brake rods are placed too close to the springs and there is frequently wear between these parts.

**Front Axles.** There were no front-axle troubles due to any inherent mechanical faults.

**Rear Axles.** No serious rear-axle trouble developed on the road other than stripping some teeth out of two ring gears in one make of car. All worn gears operated without any signs of overheating under the heaviest pulls. Increased ground clearance under most rear axles would be very desirable.

**Wheels and Tires.** All trucks for military use should have cast-steel wheels; and passenger automobiles for the army, wheels of the pressed-steel disk type.

Solid tires for trucks should be of the Giant type instead of the Dual type, as the Giant type gives better traction and apparently stands wear better than the Dual type. This was especially noticeable in the deserts, where a ridge of sand was pressed in between the two halves of the Dual tires, virtually eliminating the ground pressure of the tread, and thus reducing the tractive effort. Furthermore, the manufacturers have practically ceased production of Dual tires and are centering all their energies upon the construction of Giant tires.

**Chasses.** The frames of all vehicles completed the journey with no apparent damage. All frames were in alignment and only one case of deflection was observed. Rear bumpers should be placed on all trucks, and a stronger bumper, possibly with steel facing, should be used on military vehicles. Many towing hooks straightened under pull, and a much stronger hook should be developed.

**Bodies.** In two makes of 1½-ton trucks the body sills had to be cut out for wheel clearance and attention should be paid to this matter.

Tankers are overloaded and the center of gravity is too high. Slush was responsible for one overturning. Bumper should be in rear of faucets to protect them.

FIG. 12 DISTANT VIEW OF CONVOY GOING OVER THE GREAT SALT LAKE DESERT, AUG. 22, 1919

Whenever a train is started out for other than experimental purposes the trucks should be of the same type and tonnage, thereby eliminating the number of spare parts necessary to be carried.

For the mobile army light trucks not to exceed 2-ton capacity should be the practice. The heavier trucks should be used in the rear areas only.

With reference to shop trucks, no fixed tops should be used. The general scheme of using bows and pulleys should be followed, because the fixed top is unnecessary, as it adds to the weight of the truck and often is an encumbrance in the passage of low bridges and low-hanging branches.

The equipment on the machine-shop trucks should be rearranged to provide greater accessibility, placing the motor-generator set where the lathe now is, across the forward end of the body, and locating the lathe transversely at the rear of the body. A double bench could then be placed across the body at the center, with the drill press on one end and the grinder on the other, and four vises of various sizes and types could be attached as convenient.

Some provision should be made on all trucks to permit both sides of the hood to be folded up and securely retained in that position. This would enable two men to work on opposite sides of the motor at the same time, and would make it possible to increase the circulation of air around the motor in very warm weather. A more sturdy form of hood clip should be developed.

The rope cleats and stake pockets all worked loose and a better means of fastening them should be used.

Floor boards are too weak and should be made of heavier gauge stock. Laminated floor boards did not prove to be satisfactory.

**Equipment.** Horns loosened up from vibration, and should be more securely attached to the body.

Tool boxes should be of heavier construction in order to withstand the very hard usage to which they are subjected in the field.

## RESULTS

It is the opinion of the Ordnance Observer that the First Transcontinental Motor Convoy, as the pioneer undertaking of its kind, was a successful operation, and that the experience gained during this trip will prove invaluable, not only to the Army, but to all users of motor trucks in general.

All along the route great interest in the Good Roads Movement was aroused by the passage of the Convoy, and it was reported that several states had voted favorably on large issues of road bonds. However, the officers of the Convoy were thoroughly convinced that all transcontinental highways should be constructed and maintained by the Federal Government, because the sparsely settled states of vast area in the Rocky Mountain region are absolutely unable to finance their own section of such a project. The Townsend Bill, now before Congress, provides for just such an

FIG. 13 CLASS B TANKER RUNS OFF ROAD ON OLD RAILROAD GRADE AND TURNS OVER 270 DEG. NEAR RAWKINS, WYO.

undertaking under a Federal Highway Commission, and it is earnestly hoped that this measure may be favorably acted upon at an early date, in order that the nation may be ready for the commercial "Ship by Truck" movement.

Although the number of enlistments actually secured by the recruiting officer was not large, great interest in the various activities of the Army was stimulated throughout the regions covered by the Convoy, and reports from recruiting stations indicate that several hundred recruits were obtained as a direct result of the Convoy.

The interest of the general public in the Convoy was evidenced by a whole-hearted hospitality which never failed from beginning to end of the trip, and which was quite as spontaneous in the small towns as in the larger cities. Everybody was glad to see the trucks and the men, who were showered with every variety of refreshments all along the route. In the larger towns and cities luncheons and dinners were served, entertainments and dances given, and the clubs and many homes opened to the entire personnel. Great credit should be given to the Red Cross Canteen Service, the War Camp Community Service, the Knights of Columbus, the Y. M. C. A., the Chambers of Commerce, the Commercial Clubs, the Elks, and many similar organizations, who served the Convoy with distinction all the way "from Coast to Coast."

In the operation and maintenance of a motor-truck train many valuable lessons were learned, which warrant the following recommendations:

That extended use of triangular signs, bearing the designations of the unit using them, as road markers is invaluable.

That there should always be a very careful inspection of all

vehicles for the proper amount of gasoline, oil, and water before departure on any run, no matter how short.

That a light touring car or light delivery car replace the present motorcycle with side car, which cannot negotiate soft, sandy or muddy roads successfully, and is a single-purpose vehicle.

That Class B trucks are too heavy for use in the field, except in the rear areas, on good roads and over strong bridges.

That only trucks of the four-wheel-drive type be used with artillery because of the ease with which they negotiate any sort of rough terrain, sand or mud, in any kind of weather.

That two Class A trucks be used instead of one Class B truck wherever there are unimproved roads or doubtful bridges.

That every Service Park Unit and Repair Base should have a Militor with winch for wrecking.

experienced in starting several motors on account of low-gravity gasoline.

To give an idea of the main troubles encountered under the strenuous conditions of the run the log on July 23 is reproduced in its entirety.

Departed Clinton, 6:30 a. m. White Staff Observation Car No. 111.506 delayed in starting on account of oil-pump plunger sticking. Class B No. 414795 stalled with oil-soaked magneto 6 mi. out. Class B spare parts truck No. 414668 taken in tow by Militor on account leaking cylinder-head gasket—would not pull on hills. This truck gave some trouble yesterday, but was not repaired in Clinton. Porcelain of one AC spark plug was broken. 3 mi. west of Lowden, Class B No. 50215 stopped to clean out gasoline line. Fender fell off 2-wheel kitchen. Starting crankpin breaks on one class B and another has trouble with back-firing in carburetor. Trailmobile kitchen breaks right rear spring through all leaves in center. Class B machine shop

FIG. 14 CLASS B SPARE-PARTS TRUCK RIGHTING OVERTURNED G.M.C. AMBULANCE NO. 39399 EAST OF CHICAGO HEIGHTS, ILL., JULY 19, 1919

That the Militor should have a longer and stronger sprag, of the artillery type, similar to the spade of a gun-carriage trail; or perhaps two such sprags, one on each rear corner of the frame; that the cable reel should be placed on a squared shaft to facilitate rewinding and should be located ahead of the winch and guide sheaves which should have universal support.

That spare-parts trucks should have a stock-record card system, and that the arrangement for packing the parts be improved so that such articles as bearings may be protected with individual boxes or cartons.

That every effort be made to cooperate with carburetor manufacturers toward the production of a carburetor of the jet type suitable for use on motorcycles.

#### DAILY LOG OF THE TRIP

A log was maintained in which the incidents occurring were written day by day. It makes interesting reading and gives a clear idea of the difficulties which the train had to overcome. A few of the incidents recorded may be of particular interest; for instance, those inserted in this abridged report.

As stated, the train departed from Camp Meigs, Washington, D. C., at 8:30 a. m., July 7, 1919.

Already on July 9 some of the trucks were held back by broken accelerator springs and sticky exhaust valves losing compression. Ignition troubles of various nature developed and various types of trucks also developed considerable magneto trouble.

Considering the personnel was untrained, the driving could be called excellent.

On July 12 on one truck the main-drive shaft had been twisted off in the transmission bearing by an inexperienced driver throwing in the reverse gear and dropping in clutch while the motor was turning over at high speed on down grade. The driver did it to use the motor as a brake.

On July 17, departed Delphos at 6:30 a.m. Difficulty was

FIG. 15 MILITOR WINCH PULLS SO HARD ON CLASS B TRUCK, STUCK IN SAND, THAT IT RAISES ITS OWN REAR WHEELS OFF THE GROUND AND STANDS ON THE SPRAG. TEN MILES WEST OF NORTH PLATTE, NEB., AUG. 5, 1919

FIG. 16 VIEW OF RIKER TRUCK BELONGING TO COMPANY E, 5TH ENGINEERS, TURNED OVER IN DITCH NEAR FULTON, ILL., JULY 22, 1919

truck No. 414319 went through small culvert bridge and had to be jacked up and pulled out by Militor. Convoy escorted into Cedar Rapids by Lt. Gov. Moore, Mayor Hall, etc. Dinner served to entire command by Chamber of Commerce and Rotary Club. Made 87 miles in 10½ hr. Fair and warm. Good hard dirt roads. Arrived Cedar Rapids, Iowa, 5 p.m.

(continued on page 205)

# Turbo-Compressor Calculations

By ALLEN H. BLAISDELL, PITTSBURGH, PA.<sup>1</sup>

After pointing out the features which differentiate the turbo-compressor from the multi-stage centrifugal pump, the author takes up the study of the pressure and volume changes occurring while a fluid is passing through one stage of the former and states the fundamental energy equations involved. He then discusses the number of stages to be used in a given case and follows this with an explanation of the method of laying out a compression diagram and of subdividing it according to the number of stages to be provided for.

The function of the impeller is next discussed and in this connection expressions are derived for the actual and effective impeller radii and the axial depth of channel of any radius. Blades and blade angles are also considered and a graphical method is described for calculating the theoretical head to be developed by an impeller.

The paper concludes with a brief study of the working of free-vortex and guide-vane diffusers, and of matters to be taken into account in designing in order to obtain a turbo-compressor of the highest possible overall efficiency.

It is well known that the turbo-compressor is quite similar in its nature to the multi-stage centrifugal pump. Whatever differences exist between the two types of machines is due to the fact that one handles a gaseous medium while the other handles a practically incompressible fluid, water. Both are high-speed machines.

The impellers of multi-stage centrifugal pumps are of the same size throughout, but those of turbo-compressors should be theoretically of continually diminishing dimensions because of the decrease in volume of the fluid as it is compressed from stage to stage. Actually the impellers are divided into two or more groups and each group calculated for its own average conditions. Since the capacities of these machines rarely exceed 50,000 cu. ft. per min., and in general range from 7000 to 10,000, the single-flow type of impeller is used in most turbo-compressors.

The only other important feature which differentiates the turbo-compressor from the centrifugal pump is the arrangement made for cooling the fluid as it passes through the compressor. In the reciprocating compressor practically all cooling is accomplished by means of intercoolers located between the different stages, the water jackets of the cylinders having but slight effect on the temperature rise of the fluid which is being compressed in the cylinders. In turbo-compressors the cooling is accomplished in two ways (a) by means of cooling coils between each stage, and (b) by means of carefully designed water jackets. The water-jacket method is much more effective in the case of the turbo-compressor than in that of the reciprocating machine because the fluid being compressed has a more intimate contact with the cooling surfaces.

The discussion will be divided into three main divisions:

## A Thermodynamic Considerations

- a Study of the nature of the compression
- b Fundamental energy equations
- c Layout of compression diagram

## B Pneumatic Considerations

- a Theory of fluid flow
- b Essentials of impeller design
- c Essentials of diffuser design

## C Power Consumption and Efficiency.

### (A) THERMODYNAMIC CONSIDERATIONS

#### NATURE OF THE COMPRESSION

Fig. 1 shows in section a portion of two stages of a multi-

stage centrifugal or turbo-compressor. The fluid being compressed enters the impeller at *a* with a definite pressure, velocity and temperature. The impeller, rotating with a high speed, discharges the fluid with an increased pressure, temperature and velocity. Leaving the impeller the fluid enters the diffuser, where its velocity is greatly reduced and its pressure increased. The temperature will also be reduced somewhat, due to the cooling water which passes through the diffuser vanes. At *d* the fluid leaves the diffuser and passes down between guide vanes, during which interval it is in contact with water-cooled surfaces *f*, and suffers a still further reduction of temperature and volume. At *c* the fluid enters the succeeding impeller, where it goes through a similar cycle.

The change of state of the fluid being compressed will follow the law  $pv^n = \text{constant}$ . The value of the exponent *n* is governed by the kind of fluid being compressed, the moisture condition of the fluid and by the surrounding thermal conditions. When the fluid being compressed neither receives heat from, nor gives up heat to, surrounding bodies the compression is called adiabatic, and under these conditions  $n = 1.41$  for air. When

FIG. 1 SECTION OF PORTION OF TWO STAGES OF A MULTI-STAGE CENTRIFUGAL OR TURBO-COMPRESSOR

the nature of the compression is such that the temperature remains constant, then the compression is said to be isothermal and  $n = 1$  for all gases.

It is very difficult to say exactly what pressure and volume changes occur while a fluid is passing through one stage of a turbo-compressor. The energy transfer to the fluid occurs in the impeller, which changes the angular momentum of each fluid particle, work being done upon the fluid as a whole. As a result of this energy transfer the fluid on exit from the impeller possesses an increased pressure and velocity. But this pressure is not the total pressure developed in the stage, and herein the action in a turbo-compressor differs somewhat from the reciprocating class of machines. In the reciprocating compressor work is done by the piston upon the fluid enclosed in the compressor cylinder, first compressing the gas to the discharge pressure and then ejecting the fluid from the cylinder. In the case of the turbo-machine the impeller does work upon the fluid which results in an increase not only of pressure but also of velocity, and if the amount of work is the same in both instances it is quite evident that the pressure rise in the impeller will not be so great as in the case of the reciprocating compressor, since a portion of the

<sup>1</sup>Instructor in Mechanical Engineering, Carnegie Institute of Technology, Assoc.-Mem.-Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, December 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

energy imparted to the fluid has the kinetic form. Consequently, in order to secure as large a pressure rise as possible, use is made of a diffuser wherein no further work is done on the fluid, but a portion of its velocity head is changed over into pressure head.

It is possible to study the pressure and volume changes in the impeller of a turbo-compressor by means of a  $p$ - $v$  diagram just as in the case of the reciprocating machines. Thus, in Fig. 2,  $ABCD$  may be considered as representing what occurs in an impeller. The line  $BC$  will be the actual compression curve and must be located outside of the adiabatic  $BF$ . This is quite easy to understand, since there is likely to be but very little heat transfer through the walls of the impeller to or from the fluid because of the short interval of time which elapses while the fluid is passing through the impeller. Because of friction, impact, eddying and turbulent flow, extra work is done and this results in a compression which follows the polytropic curve  $BC$  rather than the adiabatic  $BF$ . This means that the value of the exponent  $n$  in

FIG. 2 DIAGRAM SHOWING PRESSURE AND VOLUME CHANGES IN THE IMPELLER OF A SINGLE-STAGE TURBO-COMPRESSOR

$pv^n = \text{constant}$  will be greater than 1.41. The temperature rise of the fluid must consequently be in excess of that due to adiabatic compression alone, and hence it is very essential that every effort be made to cool the fluid after it leaves the impeller, since by so doing the temperature and volume will be reduced before entrance into the succeeding stage and consequently the compression work of that stage will also be diminished.

Of the total energy imparted to the fluid in the impeller only a portion is in the form of pressure, the remainder being used up in increasing the velocity. Such being the case the expression for total work must contain a term to include the increase of kinetic energy as well as a term to cover the work of compression.

#### NUMBER OF STAGES

The number of stages to be used depends upon the total pressure to be developed by the machine and the speed of the prime mover. Since the fluid being compressed is a gas and the terminal pressure for a single stage is proportional to the density of the gas, it is evident that a large number of stages will be required if very high delivery pressures are desired.

In selecting the proper number of stages a compromise has to be made between a few stages with large-diameter impellers and a large number with impellers of small diameter. If large impellers are used the frictional losses due to the fluid drag of the fluid on the impeller will be excessive, reducing the overall efficiency of the compressor. On the other hand, if small impellers are used the pressure rise per stage will not be so large and this means an increase in the number of stages, with a consequent increase in the cost of production, but the efficiency will be better than that of the first machine. In addition to reduced frictional losses there will also be a decrease in the compression work, and this factor helps to raise the efficiency above that of the machine with a small number of stages.

For equal amounts of compression work per stage the pressure developed will not be equal but will increase from stage to stage.

If the stages are divided into two or more sets, all impellers of a single group having the same diameter, then the same fact applies, but in this case the pressure rise will be the average for the group.

#### LAYOUT OF COMPRESSION DIAGRAM FOR TURBO-COMPRESSOR

For illustrative purposes only, let us suppose that the diagram of Fig. 3 is that of a four-stage compressor. It is desired to study the peculiarities of the diagram and develop a graphical method of constructing such a diagram. The method to be explained was originated by M. de Stein.

The total energy transfer from all the impellers to the fluid passing through them is represented in the diagram by the area  $ABCDEFHGHIK$ . In other words, area  $ABC'D'$  is an equivalent  $p$ - $v$  diagram for the first stage and represents not only the work of compression in the impeller but also the increase of kinetic energy. In the same way does  $D'E'F'$  represent the energy transfer for the second stage. In other words, if  $p_1$  is the inlet pressure to the first stage, then  $p_2$  is the delivery pressure from the diffuser, and not the impeller. Consequently, the total pressure rise for the stage (impeller and diffuser) is  $p_2 - p_1$ . Such being the case,  $p_2$  will be the delivery pressure of the machine if the kinetic energy in the fluid when discharged is neglected. The pressures  $p_2$ ,  $p_3$  and  $p_4$  may be considered as the static pressures which exist between the diffuser of one stage and the entrance to the impeller of the following stage.

Good design necessitates that the areas  $ABC'D'$ ,  $DEF'D'$ , etc., shall be equal or that the energy delivered to the fluid shall be the same for each stage. The lines  $BC$ ,  $DE$ ,  $FG$  are laid out as adiabatics. If the cooling is effective they will all lie in closer proximity to the isothermal  $BM$  than the adiabatic  $BN$ . When there are a large number of stages, say eight or ten, it is allowable to assume the curve  $BJ$  (passing through points  $D$ ,  $F$ ,  $H$ ) as representing the equivalent compression curve.

To lay out the  $p$ - $v$  diagram  $ABJK$  for the machine requires that we shall know the initial pressure  $p_1$ , the initial volume  $v_1$ , in cu.

FIG. 3 COMPRESSION DIAGRAM FOR A FOUR-STAGE COMPRESSOR

ft. per lb., the delivery pressure  $p_4$  and the value of  $n$  in  $pv^n = \text{constant}$  in order that the curve  $BJ$  can be drawn.

Having laid out the isothermal and adiabatic curves it is now necessary to lay out the compression curve for the machine. In order to do this it is practically necessary to assume the position of point  $J$  of the compression curve such that

$$v_J \gamma_a (v_M - v_N) + v_N \dots \dots \dots [1]$$

where  $\gamma_a$  = adiabatic efficiency and  $v$  = volume in cu. ft. per lb.

When the compression is adiabatic, if the final temperature is  $T_N$  deg. abs., the adiabatic efficiency, or ratio between the theoretical internal work and the work actually furnished for the compression, can be expressed by

$$\gamma_a = \frac{T_N - T_1}{T_J - T_1} \dots \dots \dots [2]$$

where

$T_J$  = final temperature in deg. abs. with adiabatic compression  
 $T_N$  = final temperature in deg. abs. with actual compression  
 $T_i$  = initial temperature in deg. abs.

If frictional resistances are considered, then the value of  $\tau_p$  as calculated from [2] will be increased about 3 per cent.

## (B) PNEUMATIC CONSIDERATIONS

### DIVISION OF THE PRESSURE-VOLUME DIAGRAM

On completion of the actual compression diagram  $ABJK$  (Fig. 5) it is next necessary to divide its area into the same number of parts as there will be stages or groups of stages in the compressor. In this instance it is four.

The total energy head developed by a single impeller or group of impellers can be stated in the form

$$H = \frac{p}{\gamma_m} = K \frac{u^2}{g} \dots \dots \dots [3]$$

where

$$K = \tau_p \times \phi$$

and

$\gamma_m$  = mean density for a single stage, or group of stages  
 $u$  = peripheral velocity of the impeller (or impellers) in ft. per sec.

FIG. 4 METHOD OF LAYING OUT COMPRESSION DIAGRAM FOR TURBO-COMPRESSOR

$\tau_p$  = pneumatic efficiency for a single stage, or group of stages

$\phi$  = form factor determined by the blade shape, angles, etc.  
 $p$  = pressure rise for a single stage, or group of stages.

It is evident from Equation [3] that the compression diagram must be so divided into areas that the law  $pv = \text{constant}$  shall hold true; that is, all the areas into which the  $pv$ -diagram is divided must be equal.

The following graphical method can be used with great facility in carrying out this subdivision, particularly when there are a good many stages to be considered.

Let  $ABJK$  (Fig. 5) represent the compression diagram for the compressor. We will assume, as before, that the machine has four stages only and proceed to divide this diagram into parts such that the areas will all be equal.

Divide the distance  $KA$  into any convenient number of equal lengths, say, six, marked by the figures 1, 2, 3, etc. Through these points draw horizontal lines 1-1, 2-2, 3-3, etc., cutting the diagram up into six trapezoidal areas which can be quite easily converted into equivalent rectangles as indicated in Fig. 6.

The areas of these rectangles are to each other as their bases. Reduce these bases by one-half, say, and add to each one of these the sum of the reduced lengths of the preceding ones. Through the ends of the lines thus drawn pass a smooth curve,  $AabedeC$ . The length of any horizontal such as  $KC$  represents to scale the area between it and the lines  $JB$ ,  $BA$ , and  $AK$ . In other words, because of the construction the length  $KC$  represents the area of the compression diagram. Such being the case, if we divide  $KC$  into the same number of equal parts as there will be stages, or groups of stages (in this instance, four) and through the division points  $H$ ,  $F$ ,  $D$ , drop verticals intersecting the curve  $AC$  at  $I$ ,  $G$ , and  $E$ , respectively, then horizontals through  $I$ ,  $G$ , and  $E$  will

FIG. 5 PRESSURE-VOLUME DIAGRAM FOR COMPRESSOR

divide the compression diagram into four sections whose areas will be equal. The lengths  $AI$ ,  $IG$ ,  $GE$ , etc., will represent the total pressure head to be developed by each stage, or group of stages.

If the line  $AB$  represents the total volume of fluid taken into the compressor, then  $mm$ ,  $nn$ ,  $oo$ ,  $pp$ , etc., will represent, to the same scale, the average volume for the various stages, or groups of stages. On the other hand, if  $AB$  represents the specific volume of the fluid drawn into the first stage, then  $mm$ ,  $nn$ ,  $oo$ ,  $pp$ , etc., will represent to the same scale the average specific volumes of the different stages.

If  $V_{m1}$ ,  $V_{m2}$ ,  $V_{m3}$ , etc., are the mean specific volumes just defined,  $V_{m1}$ , being the mean specific volume for the first stage, then the mean densities are

$$\delta_1 = \frac{1}{V_{m1}}; \quad \delta_2 = \frac{1}{V_{m2}}; \quad \delta_3 = \frac{1}{V_{m3}}; \text{ etc. } \dots \dots [4]$$

It has already been stated that the pressures developed per stage are proportional to the fluid densities. Hence the ratio of the total pressure developed in one stage to that of the following or preceding stage must be the same as the ratio of the mean densities. If  $p_1$ ,  $p_2$ ,  $p_3$ , etc., are the discharge pressures per stage, we have

$$\frac{p_1}{p_2} = \frac{\delta_1}{\delta_2}; \quad \frac{p_2}{p_3} = \frac{\delta_2}{\delta_3}; \quad \frac{p_3}{p_4} = \frac{\delta_3}{\delta_4}; \text{ etc. } \dots \dots [5]$$

where  $p_1$  and  $\delta_1$  are the pressure and density of the fluid on entrance into the first stage.

If a group of stages is made up of  $n$  impellers and  $p$  is the total pressure increase for the group, we can assume the average increase per impeller and diffuser (or stage) as given by

$$\Delta p = \frac{p}{n} \dots \dots \dots [6]$$

In reality the pressure increases will not be the same, as we already know, but the resulting error has no effect on the accuracy of the calculations as a whole. By using Equation [6] we virtually assume that the fluid is incompressible for a group of

stages, or that the mean density of one stage is the same as those of the remaining stages of the group.

IMPELLERS AND DIFFUSERS

In the design of impellers and diffusers for turbo-compressors we are forced to depend on the theory of centrifugal pumps, which at its best is far from being satisfactory or complete for centrifugal pumps even, and of course is far less so when applied to turbo-compressor calculations. However, by making certain assumptions it is possible to utilize the theory with quite satisfactory results.

In order to simplify the analysis of fluid flow it is necessary to make the following assumptions:

- a That the fluid has stream-line motion, i.e., the fluid particles move in non-intersecting curves
- b That the fluid will, since it is elastic, completely fill the channel of flow

FIG. 6 GUIDE-BLADE CONSTRUCTION, SHOWING EFFECTIVE IMPELLER RADII

- c That the motion of the fluid is steady, i.e., each fluid particle has the same mean velocity as every other particle which is moving along with it through any section and the static pressure is the same at all points of a section which is at right angles to the fluid flow.
- d That the fluid is non-compressible.

THE IMPELLER

The function of the impeller is to impart a certain amount of energy to the fluid passing through it, with a maximum of efficiency. That is, friction, fluid impact, and turbulence should be reduced to a minimum.

On the assumption that the speed of rotation and the rate of fluid flow are known, there will be derived expressions for the actual and effective impeller radii, and the axial depth of the impeller channel at any radius. In addition to these there will also be given a brief discussion on blades and blade angles, together with the explanation of a graphical method for calculating the theoretical head to be developed by an impeller.

If we assume the impeller discharge to be zero, then from an equation given in the complete paper we obtain

$$W = \frac{144 \rho_1 v_1}{\eta_i} \cdot \frac{n}{n-1} \left[ \left( \frac{\rho_2}{\rho_1} \right)^{\frac{n-1}{n}} - 1 \right] \dots \dots \dots [7]$$

where  $\eta_i$  = impeller efficiency, being practically identical with  $\eta_R$ , but applying to the conditions of zero discharge only. This expression actually represents the work of compression performed in the impeller against the centripetal forces of the fluid particles. Since these forces vary from a minimum at the impeller entrance to a maximum at the discharge, the work done in forcing one pound of fluid from entrance to exit is equal to the average value of the centripetal force multiplied by the radial distance through which the pound of fluid is to move (with a negligible velocity). Such being the case, we have

$$F \times (R_2 - R_1) = W \dots \dots \dots [8]$$

where

$$F = \text{centripetal force} = \frac{N^2}{5908} (R_2 + R_1)$$

$R_2, R_1$  = actual outer and inner radii of the impeller in feet

$N$  = r.p.m. of impeller

$W$  = work of compressing 1 lb. of fluid in the impeller in ft.-lb.

Substituting in [8] the value for  $W$  given by [7] we finally get, if  $R_2 = aR_1$  and  $\tau_1 = 0.75$ ,

$$R_2 = \frac{1095}{N} \sqrt{\frac{\rho_1 \tau_1}{(1 - \tau_1)}} \left[ \left( \frac{\rho_2}{\rho_1} \right)^{\frac{n-1}{n}} - 1 \right] \dots \dots \dots [9]$$

The value for  $R_2$  given by [9] must be checked from the strength standpoint in order to fortify against the possible occurrence of dangerous stresses in the impeller at excessive speeds of rotation. In fixing upon final definite values for  $R_2$  and  $R_1$ , care must be taken to see that the inlet area of the propeller is not too restricted, thus choking the fluid flow and causing an unnecessary loss of head at the impeller entrance.

The effective impeller radii  $r_2, r_1$  (Fig. 6) are those at which the velocities  $w_2, u_2, r_2, w_1, u_1, r_1$  are calculated and are not the same as the actual radii  $R_2, R_1$ . If an impeller is designed with velocity diagrams based on the radii  $R_2, R_1$ , it will be found that the impeller will not develop the desired head without an increase in the rated speed. It should be noted that if the impeller blades are radial at exit then the actual and effective radii (outer) will coincide. The determination of  $r_2$  and  $r_1$  is mostly a matter of judgment and will be taken up later on in the paper.

IMPELLER BLADES

Just what shape of blade should be used is largely dependent upon the type of characteristic desired. In Fig. 7,  $a$  and  $b$ , are shown typical constant-speed characteristics  $AB$  and  $AC$ . They represent in a general way how the pressure varies with the discharge from a single stage, curve  $AB$  referring to curved-back

FIG. 7 TYPICAL CONSTANT-SPEED CHARACTERISTICS SHOWING HOW PRESSURE VARIES WITH THE DISCHARGE FROM A SINGLE STAGE

blades and  $AC$  to radial blades. Both curves are supposed to show the combined effect of the impeller and diffuser. If the diffuser has been properly designed to suit the impeller and the casing, the characteristics  $AB$  and  $AC$  will clearly indicate the effect of the blade shape on the nature of the pressure characteristic. It will be noticed that the slope of  $AB$  tends to grow steeper from the very first and the fact that it does rise at all is due to the effect of the diffuser. This so-called "drooping characteristic" is always typical when backward-curved blades are used. In the case of the radial blade the characteristic  $AC$  has a decided rise from point  $A$  and only starts downward some distance beyond  $A$ . Lines  $HH$ , in both figures, represent in a general way the relative locations of the maximum possible discharge pressure and the corresponding magnitude of the discharge. With leaning-back blades the minimum possible discharge (accompanying the maximum possible pressure) from the com-

pressor is about 30 per cent of the normal. With radial blades the minimum discharge ranges between 40 and 60 per cent of the normal, the normal discharge being indicated by lines  $mn$  for both cases. The location of this lower discharge limit is of much importance, for if the volume is reduced any further, "surging" or "pumping" ensues, with consequent severe oscillations of the machine.

The radial type of blade is used to a large extent in turbo-blowers where the discharge pressure seldom exceeds 40 lb. per sq. in. gage. By using radial blades it is possible to use larger impeller diameters for a given speed of rotation. This means fewer stages with impellers of a simple but very strong construction.

The claim is sometimes made that the curving back of the blades at the outlet secures only a very small increase in the mechanical efficiency, but that this is accompanied with a relatively greater loss of manometric efficiency. This fact may be of importance in the case of fans and blowers, but it does not apply with equal emphasis in the case of turbo-compressors where the absolute velocity of discharge from the impeller is kept down to as small a value as possible by use of leaning-back blades in the impellers. Under any circumstances it is very difficult to convert much more than 50 per cent of the kinetic energy of the fluid, when discharged from the impeller, into pressure. When diffusers are used as a means of carrying out the conversion it is quite necessary that the absolute discharge velocity from the impeller shall be a minimum, otherwise there will be large pressure-head loss because of impact, eddying, etc., as will be more fully explained later on in the discussion.

If radial vanes are used, however, it is essential that they should be curved at the inlet to suit the relative velocity of the fluid to the vane at that point. Some manufacturers divide the blade into two parts, making the larger external portion straight and radial, a form that can be easily machined, and attaching to this a curved part at the inlet, which being small can be readily machined.

The total fluid head against which the impeller must work can be expressed in the following three ways:

$$H = \frac{v_2^2 - v_1^2}{2g} + \frac{144}{\gamma_m} (p_2 - p_1) + J (i_2 - i_1) \dots \dots \dots [10]$$

$$H = \frac{v_2^2 - v_1^2}{2g} + \frac{u_2^2 - u_1^2}{2g} - \frac{w_2^2 - w_1^2}{2g} + J (i_2 - i_1) \dots \dots [11]$$

$$H = \frac{u_2(u_2 - v_2 \cos \alpha_2)}{g} + \frac{u_1(u_1 - v_1 \cos \alpha_1)}{g} + J (i_2 - i_1) \dots [12]$$

where

$H$  = theoretical head in feet of fluid (can be in terms of water head)

$v_2, v_1$  = absolute velocities of exit from and entrance to impeller, respectively

$u_2, u_1$  = peripheral velocities at exit and entrance of impeller, respectively

$w_2, w_1$  = relative velocities of discharge from and entrance to impeller, respectively

$i_2, i_1$  = sensible heat contents per lb. of fluid in B.t.u.

$J = 778$

$\alpha_2, \alpha_1$  = angle made by vectors of  $v_2$  and  $v_1$  with those of  $u_2$  and  $u_1$ , respectively

Equations [10], [11] and [12] are, if the sensible-heat factor is neglected, well-known standard equations for centrifugal pumps and their derivation as given will be found in any textbook on turbine pumps. The increase in sensible heat is assumed to be that due to adiabatic expansion and friction in the impeller. If there are a large number of stages in the compressor the change in sensible heat per stage, due to adiabatic expansion, can be omitted when using the above equations. That due to friction is a very uncertain quantity and can be approximated only.

The head  $H$  is the head which must be imparted to the impeller in order to obtain the actual head  $H_A$ ; that is,  $H$  must cover all pneumatic losses. If we let  $H_L$  represent the loss of

head due to resistances to fluid flow, etc., and  $\eta_p$  the pneumatic efficiency, then

$$\eta_p = \frac{H_A}{H} = \frac{H_A}{H + H_L} \dots \dots \dots [13]$$

The pneumatic efficiency is analogous to the hydraulic efficiency of centrifugal pumps and is a measure of the pneumatic losses in the compressor. These losses cause a reduction in  $H$  due to (a) the frictional resistances offered by the interior surfaces of the machine to the movement of the fluid, and (b) to too abrupt changes in the fluid path both in direction and cross-section.

In calculating the fluid velocities of entrance to and discharge from impeller, it is assumed, as mentioned before, that the fluid particles move through and discharge from the impeller with the same relative positions. In other words, the velocity at any cross-section of the impeller channel is the same for all the fluid particles. Of course, this can only be true for an impeller with an infinite number of blades of infinitesimal thickness. Actually, between any two blades the fluid stream has its maximum velocity at the center of the stream, while those particles adjacent to the blades are retarded in their motion due to the surface drag of the blade surfaces. From a practical standpoint, however, it is sufficient to assume that all the fluid particles have the same velocity as those of the middle filament. Such being the case, the effective radii,  $r_p, r_i$  of the impeller will be different from actual exterior radii  $R_2$  and  $R_1$  (Fig. 6). The entrance- and exit-velocity diagrams should be laid out from the points  $a$  and  $b$ , Fig. 6. If this is done there results an increase in  $\eta_p$ , bringing it closer to the value desired. Line 1-1 (Fig. 6) is drawn normal to the blade at point 2, while 3-4 is drawn normal to the blade at point 3. Points  $x$  are located at the centers of these lines. It should be noted that if the foregoing theory is to be applied with the expectation of good results, the impeller blades at entrance and exit must have relatively small divergence, thus insuring that the velocities across these sections will be fairly uniform.

# DIFFUSERS

On discharge from the impeller the energy content of the fluid, as previously shown, is largely in the potential and kinetic form. For a perfect impeller the division between the two would be nearly equal. Actually, however, this is not the case, the potential energy being smaller in value than the velocity energy. That is, the pressure head will be less than the velocity head. In order to convert part of this velocity head into pressure head, use is made of so-called diffusers. These can be made in two forms, the free vortex and the guide vane. As a matter of fact, the second or guide-vane diffuser is really at normal loads a free-vortex diffuser, providing the guide vanes have been properly designed. Of course, this is not the case under ordinary conditions, particularly in a multiple-stage machine where it is desirable that the discharge from the diffuser shall be radial, or at least not far from radial.

On discharge from the impeller a fluid particle, if unhindered, will trace out a spiral path providing the space surrounding the discharge side of the impeller has sufficient radial depth. In other words, the fluid as a whole will have a free vortical motion and it can be shown that the path of any fluid particle is a logarithmic spiral, the equation of which is

$$r = r_0 e^{\theta} \dots \dots \dots [14]$$

where

$e = 2.7183$

$k = \text{constant}$

$\theta$  = angle of radius vector with entrance position.

With free vortical motion of the discharge the maximum possible gain of pressure is as given by one of the equations in the complete paper. Due to instability of flow, friction of side walls, impact, etc., however, which cause the stream lines to be widely divergent from the theoretical, the gain of pressure given by this equation is not attainable in practice. If a free-vortex diffuser is used it is essential that its radial depth be sufficient for the vortical motion to develop and thus secure as large energy con-

version as possible. The axial depth of the diffuser on the entrance side should be the same or slightly greater than that of the impeller discharge. This axial depth may remain constant or gradually diverge from inlet to outlet of diffuser. It is of course quite essential that the inner surfaces of the diffuser shall be as smooth as possible in order that friction shall be eliminated.

Because it is practically impossible to obtain non-turbulent motion in a free-vortex diffuser the use of guide vanes has been introduced. These are located in the diffuser channel and divide it up into several separate sections, through which the fluid can flow with a reduced tendency to become turbulent. As a consequence the conversion efficiency is higher than in the case of the diffuser without guide vanes. In practice it is difficult to transform much more than 50 per cent of the kinetic energy possessed by the fluid on entrance to the diffuser into pressure energy by the time the fluid is discharged. With a guide-vane diffuser the best conversion efficiency is obtained at normal load when the fluid leaves the impeller in such a direction as to enter the diffuser sections with a minimum of shock, eddying, etc.

The number of guide blades should be sufficient to give the desired uniformity of flow without undue friction, usually one-half to two-thirds as many guide blades as impeller blades. If the same number of blades are used in both there may result severe periodic impulses or vibrations due to the fact that the clear cross-section of the fluid channels at discharge of impeller and entrance to diffuser are increasing and decreasing in unison.

Theoretically the shape of the guide blades should be that of a logarithmic spiral to conform with the free path which the fluid tends to follow on leaving the impeller. Actually, the blade shape is governed by other requirements. A favorite form of guide-blade construction is that shown in Fig. 6, and is similar to those used on turbine pumps. The cavity inside the blades is connected with the cooling-water circuit and thus some reduction in the temperature of the fluid is obtained while it flows through the diffuser. The blade curves are customarily volutes or involutes on the entrance side of the diffuser and a combination of circular arcs and straight lines for the remainder of the blade length.

### (C) POWER CONSUMPTION AND EFFICIENCY

In order to compete successfully in the industrial field with the reciprocating compressor it is of great importance that the overall efficiency of the turbo-compressor be made as high as possible. That is, the difference between the compressor input (work delivered to the compressor) and output (work obtained from compressor) should be reduced to a minimum. The area of the  $p$ - $v$ -diagram represents the useful work done in the compressor, but it does not include the pneumatic, mechanical and volumetric losses. If  $\eta_p$ ,  $\eta_m$ ,  $\eta_v$  are the pneumatic, mechanical, volumetric and overall efficiencies, respectively, then the shaft horsepower must be given by the following expression neglecting the kinetic energy of discharge:

$$\text{Shaft Hp.} = \frac{0.261 \times L \times p_1 v_1}{\eta} \times \frac{n}{n-1} \left( \left( \frac{p_2}{p_1} \right)^{\frac{n-1}{n}} - 1 \right) \quad [15]$$

where

$\eta$  = varies between 0.55 and 0.65 and equals  $\eta_p \times \eta_m \times \eta_v$   
 $L$  = lb. of fluid compressed per sec.

$p_1$  —  $p_2$  = total pressure rise in the machine in lb. per sq. in. abs.  
 $n$  = compression exponent and is calculated from an equation given in the complete paper.

The mechanical efficiency  $\eta_m$  is the ratio between the total power actually delivered to the fluid and the shaft or brake horsepower. It is a measure of the power losses, made up of rotation loss (friction between outer surfaces of impellers and the surrounding fluid) and bearing loss or similar losses due to friction between metal surfaces. The rotation loss will vary between 10 per cent and 20 per cent of useful output of the machine, being determined by the density of the fluid, the speed of rotation, and the impeller diameters. For a single impeller it can be calculated very approximately from the following expression:

$$\text{Friction Hp.} = 0.44 \times 10^{-8} \times \delta_m \times N^4 \times D^4 \dots [16]'$$

where

$N$  = r.p.m.

$D$  = impeller diameter in ft.

$\delta_m$  = mean density of fluid for the stage.

Equation [16] is based upon experiments with constant-thickness disks in open air. It is readily seen from [16] why it is preferable to employ a large number of small-diameter impellers in place of a lesser number with large diameters. With a given discharge any increase in pressure must be accompanied by either an increase in speed or else an enlargement of the impeller diameter. Since the frictional resistance varies as the speed cubed and the impeller diameter to the fifth power, it is more economical to use high speeds with small impellers.

The volumetric efficiency is, of course, the ratio of the fluid actually delivered by the compressor to that taken into the compressor, and will vary between 96 and 98 per cent, a good average being 97 per cent. Most of this leakage will occur in the last stage between the inlet to that stage and the atmosphere, and is not materially affected by the number of stages.

Under ideal conditions the compression would follow the isothermal curve  $BM$  on the  $p$ - $v$ -diagram, Fig. 3. The compression efficiency will be, when referred to the isothermal,

$$\eta_e = \frac{\text{isothermal work}}{\text{actual work}} = \left( \frac{n-1}{n} \right) \frac{T_1}{T_2 - T_1} \log \frac{p_2}{p_1} \dots [17]$$

and will vary between 60 and 67 per cent.

The need of cooling the fluid as it passes through the compressor is emphasized by [17]. The heating of the fluid during compression renders it difficult to obtain efficiencies which are materially better than those attainable with reciprocating machines of modern construction. The amount of heat to be dissipated is more than that due to adiabatic compression since the mechanical energy loss due to short-circuiting, eddy currents, fluid impact, and fluid friction reappears as heat energy stored very largely in the fluid itself. By careful design of the cooling-water passages in the casing and diffusers, and by use of a large number of stages, it is possible to carry off most of this sensible heat. In spite of the use of a water-cooled housing, the temperature rise of the air in some turbo-air compressors has been over 200 deg. Fahr., the inlet temperature being in the neighborhood of 70 deg. Fahr. In the first few stages the cooling effect is small because of the small temperature difference between the air and the cooling water, but in the later stages the compression approaches very closely to being isothermal, as we already know, and the temperature of the air when discharged will range between 150 deg. Fahr. and 175 deg. Fahr. for discharge pressures of from 75 to 120 lb. per sq. in. gage.

What the Bureau of Mines has done for the great coal-mining industry, chiefly through investigations at the experiment station at Pittsburgh, Pa., has been published in numerous reports issued by the Bureau. Some of the more important accomplishments have been the development and introduction of permissible explosives for use in gaseous mines, the training of thousands of coal miners in mine-rescue and first-aid work, and the conducting of combustion investigations, aimed at increased efficiency in the burning of coal and the effective utilization of our vast deposits of lignite and low-grade coal. How vast are the deposits of low-grade ores being made available through the experiment stations is shown by the work assigned to the station at Minneapolis, Minn. The primary purpose of this station is to devise methods of utilizing low-grade iron ores. It has been estimated that the reserves of low-grade magnetic iron ores in Minnesota alone amount to some forty billion tons, but until recently these ores have been untouched because no process of treating them profitably has been devised. The Minneapolis station has already demonstrated that one process for utilizing the great deposits of manganese iron ore on the Cuyuna Range is metallurgically possible.

Nature of Stresses Developed by Seismic Shocks; Theory of Design of Chimneys to Withstand Such Stresses; Particulars Regarding Chimneys in Which Theory Has Been Applied

By C. R. WEYMOUTH,<sup>1</sup> SAN FRANCISCO, CAL.

*The studies of the Japanese Imperial Investigation Committee on the nature of the stresses developed in chimneys in consequence of earthquakes are summarized by the author, who also examines the conclusions of the committee in the light of data on failures of chimneys secured from inspections of wrecks caused by the San Francisco earthquake of 1906. An advancement to the theory developed by Professor Omori, Chairman of the Japanese Committee, on the design of chimneys to withstand earthquakes, is then presented. This assumes that the chimney, instead of being looked upon as rigid, should be considered as a body oscillating about the center of percussion. Reference is made in the paper to the design of various chimneys where the theory outlined has been applied.*

**B**ECAUSE of the prevalence of earthquakes in Japan, and the immense damage resulting from them to buildings and other structures, the Japanese Government, a number of years ago, created the Imperial Earthquake Investigation Committee with a view to having it undertake a scientific study of earthquake phenomena, as well as of the effect of earthquakes on structures, etc. The Committee's reports would fill a good-sized volume. Many of these have been translated into English, and are obtainable at a few of the leading libraries in this country. Professor Omori, chairman of this committee, is the world's greatest authority on earthquake problems.

Although this subject is one of more or less academic interest, there are, however, certain localities in this country, mainly on the Pacific Coast, and many foreign localities, where the design of structures necessitates a careful consideration of the forces due to earthquakes. With the increasing tendency to invest American capital in foreign countries, American engineers will be required to design structures to withstand earthquakes.

A brief review of the work of Professor Omori, together with certain data pertaining to the San Francisco earthquake of 1906, a discussion of what the writer believes to be a limitation in a portion of Omori's work, and also an advancement in the theory of the design of chimneys to withstand earthquake are presented in this paper.

Earthquakes are due to various causes, the principal one being a slippage of the crust of the earth along fault lines. Earthquakes, of course, vary from mild trembles, barely perceptible and lasting but a few seconds, to violent shocks lasting several minutes and capable of demolishing very substantial structures. The principal movement is in a horizontal plane, but the vibration occurs in a number of directions in the same plane. There is generally a slight, but sometimes a severe, movement in a vertical direction, and also a severe twisting effect. On account of the combination of horizontal and vertical motion, earth waves visible to the eye frequently occur during earthquakes.

Earth movements are recorded at most astronomical observatories by means of seismographic instruments which record the displacement of the earth in three coördinates by measuring the amplitude, frequency, and duration of the earth wave.

By means of various earthquake records, values have been established for the maximum rate of acceleration of an earth particle, the maximum amplitude of an earth particle during a complete vibration, and the time for the complete period of vibration; and from these data it is possible to estimate approximately the stresses and strains in simple structures subject to earthquake shock. A sufficient number of earthquakes have been recorded and classified during recent years to make known the

maximum intensity of shock experienced in certain localities, and the best that an engineer can do is to design a structure based on recorded experience. There will, however, always be the doubt as to whether some future earthquake may not be more severe than those which have been recorded in the past.

The most severe earthquake recorded in Japan was the Mino-Owari great earthquake of 1891, for which Omori gives the following estimates:

Displacement of an earth particle .....	233 mm.
Complete period of the principal motion, being a wave cycle .....	1.3 sec.
Duration of earthquake .....	4 min. 30 sec.
Maximum acceleration observed at different localities ranged from .....	3,000 to 10,000 mm. per sec. per sec.

For the purpose of classifying various earthquakes Omori has devised an absolute scale of earthquake intensities as follows:

The following absolute scale of destructive earthquakes, or the relation between the maximum acceleration of the earthquake motion and the damage produced, has been deduced chiefly from analysis of the Mino-Owari earthquake, the intensity being arbitrarily divided into seven classes. It is to be noted that the scale applies principally to Japan.

- 1 Maximum acceleration, 300 mm. per sec. per sec. The motion is sufficiently strong to cause people generally to run out of doors. Brick walls of bad construction are slightly cracked; plasters of some old dōzō (godowns) shaken down; furniture overturned; wooden houses so much shaken that cracking noises are produced; trees visibly shaken; waters in ponds rendered slightly turbid in consequence of the disturbance of the mud; pendulum clocks stopped; a few factory chimneys of very bad construction damaged.
- 2 Maximum acceleration, 900 mm. per sec. per sec. Walls in Japanese houses are cracked; old wooden houses thrown slightly out of the vertical; tombstones and stone lanterns of bad construction overturned, etc. In a few cases changes are produced in hot springs and mineral waters.
- 3 Maximum acceleration, 1200 mm. per sec. per sec. About one factory chimney in every four is damaged; brick houses of bad construction partially or totally destroyed; a few old wooden dwelling houses and warehouses totally destroyed; wooden bridges slightly damaged; some tombstones and stone lanterns overturned; shoji (Japanese paper-covered sliding doors) broken; roof tiles of wooden houses disturbed; some rock fragments thrown down from mountain sides.
- 4 Maximum acceleration, 2000 mm. per sec. per sec. All factory chimneys are broken; most of the ordinary brick buildings partially or totally destroyed; some wooden houses totally destroyed; wooden sliding doors and shoji mostly thrown out of the grooves; cracks 2 or 3 in. in width produced in low and soft grounds; embankments slightly damaged here and there; wooden bridges partially destroyed; ordinary stone lanterns overturned.
- 5 Maximum acceleration 2500 mm. per sec. per sec. All ordinary brick houses are very severely damaged; about 3 per cent of the wooden houses totally destroyed; a few terra, or Buddhist temples, thrown down; embankments severely damaged; railway lines slightly curved or contorted; ordinary tombstones overturned; ishigaki, or masonry walls, damaged here and there; cracks 1 or 2 ft. in width produced along river banks; waters in rivers and ditches thrown over the banks; wells mostly affected with changes in their waters; landslips produced.
- 6 Maximum acceleration, 4000 mm. per sec. per sec. Most of the terra, or Buddhist temples, are thrown down; 50 to 80 per cent of the wooden houses totally destroyed; embankments shattered almost to pieces; roads made through paddy fields so much cracked and depressed as to stop the passage of wagons and horses; railway lines very much contorted; large iron bridges destroyed; wooden bridges partially or totally damaged; tombstones of stable construction overturned; cracks a few feet in width formed in the ground, accompanied sometimes by the ejection of water and sand; earthenware buried in the ground mostly broken; low grounds, such as paddy fields, very greatly convulsed, both horizontally and vertically, sometimes causing trees and vegetables to die; numerous landslips produced.

<sup>1</sup> Chief Engineer, Chas. C. Moore & Co. Engineers. Mem. Am. Soc. M. E.

7 Maximum acceleration much above 4000 mm. per sec. per sec. All buildings, except a very few wooden houses, are totally destroyed: some houses, gates, etc., projected 1 to 3 ft.; remarkable landslides produced accompanied by faults and shears of the ground.

In the above scale of the seismic intensity, the earthquake motion has been assumed to be entirely horizontal. This supposition would not, except in places very near to the epicenter, cause sensible errors in the result.

A complete report was made of the San Francisco Earthquake by the California Earthquake Commission. This report, which has been published by the Smithsonian Institute, gives numerous charts, diagrams, photographs along fault lines and of wrecked structures, etc., and its study will be of value to any one desiring to pursue this subject further.

Seismographic records were almost valueless for the San Francisco earthquake because practically all of the instruments at the local observatories were put out of commission by the intensity of the shock, the full amplitude greatly exceeding their limits of movement. Omori visited San Francisco soon after the earthquake and, judging from the damage done, estimated the complete amplitude of the most severe shock to have been about 4 in., and the complete period of vibration of an earthquake wave about 1 sec. He also noted shear along the fault lines at different points from 16 to 20 ft.

Professor Lawson, a member of the California Earthquake Commission, estimated, from the Omori scale, that the acceleration for various formations in San Francisco had been as follows:

Foundation	Acceleration mm./sec. <sup>2</sup>
Serpentine .....	250
Made land .....	300
Marsh .....	1100
Sandstone .....	250 to 600
Made land .....	2900
Sand .....	600
Sandstone .....	400
Sand (Mission Valley) .....	1100
Marsh .....	3000
Sundry solid rocks .....	250

It will be noted from these data that earthquake shocks are least severe on structures built on rock foundations and most severe on structures built on loose or filled ground.

Omori discusses the force due to earthquake as impulsive or gradual, defining the former as a force applied to an elastic body so rapidly that it is finished in a time interval infinitely small in comparison to the period of natural vibration of the body, and the latter as a force applied so slowly that the body assumes a position of equilibrium without being thrown into vibration.

Within moderate limits of intensity of earthquake shock, Omori shows that structures are likely to fail which have a natural period of vibration materially less than the period of the earthquake, and structures are not likely to fail which have a natural period of vibration equal to, or greater than, the period of the earthquake. It is apparent that structures in the former class are short in comparison with their width, or diameter, and, until failure occurs, are accelerated throughout their mass by the earthquake vibration, inducing stresses resulting from the acceleration of the mass of the structure as a whole. Structures of the latter class are generally tall in comparison with their width, are more or less flexible, and, owing to their natural period of vibration with respect to the earthquake period of vibration, are able to yield in a measure to the earth movement, and are not accelerated as a whole at a rate equal to the earth's acceleration, and, consequently, are stressed to a less extent than in more rigid structures.

Omori brings out the well-known proposition that a force impulsively applied to an elastic body produces a stress double that caused by the same force when gradually applied, and further states that since brick fractures immediately the limit of elasticity is exceeded, the strength of a brick column against a force applied impulsively is half that against the same force applied gradually.

Having reduced the investigation of earthquakes to a basis of numerical acceleration and stated periods of vibration, Omori proceeds to show that for any given structure, such as a vertical prism resting on its base, the force necessary to accelerate the mass is to be computed from the well-known formula that the

force is equal to the total mass of the structure, multiplied by the acceleration, divided by  $g$ ; assuming, of course, that the mass is accelerated as a whole. This force may be considered as applied at the center of gravity, and it exerts a turning moment at the base of the prism equal to the computed force multiplied by the height of the center of gravity above the base.

In one of his reports Omori gives the results of investigation of forty-nine self-supporting brick chimneys. These failed at points from 24 per cent to 94 per cent of the height of the chimney, the average failure being at a point about two-thirds of the height of the chimney, while practically none of the chimneys failed at the base. He points out that the point of failure corresponds approximately to the center of percussion of the chimney with reference to a horizontal axis at the base of the chimney. Unfortunately, no self-supporting steel chimneys nor reinforced-concrete chimneys were in existence in Japan during the severe earthquake shocks of 1891 and 1894.

Omori shows that the failure of chimneys at the center of percussion instead of at the base of the chimney indicates a tendency to oscillate, as it were, about the center of percussion. There is a whip-snapping effect of the upper portion of the chimney which may cause a condition of resonance. In chimneys which have failed portions of the top of the chimney have been thrown down, striking the ground never at a great distance from the base of the chimney.

The writer investigated the failures of a number of chimneys in the San Francisco earthquake of 1906, and found that brick chimneys failed in about the same manner as observed by Omori. The tallest chimney investigated was 240 ft. in height, and failed at a point about two-thirds its height. Many of the large brick chimneys in the San Francisco District failed, although a few on rock foundation and especially well built did not fail by having a portion of the chimney height demolished; but the chimneys that did not suffer in this way were at least cracked either vertically or horizontally.

There were no reinforced-concrete chimneys in San Francisco at the time of the earthquake, and but one large self-supporting steel chimney, this being 10 ft. in diameter by 120 ft. in height. This chimney, although brick-lined, was not injured by the earthquake. A 150-ft. self-supporting steel chimney at the Mare Island Navy Yard was uninjured by the earthquake. A 217-ft. brick-lined self-supporting steel chimney at Salinas, Cal., likewise was uninjured by the earthquake.

Omori made an interesting series of experiments with brick columns on a shaking table, duplicating in effect earthquake motions of varying intensities. The results of these experiments are too elaborate for presentation in this paper. They showed conclusively that estimates of the tensile strength of brickwork are exceedingly uncertain and undependable, owing to the variation in the character of workmanship in laying the brick.

Omori has measured the natural period of vibration of a number of self-supporting brick chimneys. One chimney 50 ft. in height was found to have a natural period of vibration of about one second.

Recently a very tall concrete chimney has been erected in Japan for the Kuhari Mining Co., Sagamosaki, in the Oita Prefecture, Kyushu. The main shaft has a height of 550 ft.: the inside diameter at the top is 23 ft. 6 in.; the base is circular and 95 ft. in diameter; the natural period of complete vibration of the chimney was observed by Omori to be 2.5 sec. The range of motion or double amplitude of the top of the chimney was 1 in. at a strong gale of 24 m. per sec., but it reached 7.7 in. at a hurricane wind blowing 35 m. per sec. The chimney is located on hard rock, on which it is estimated an earthquake movement would be comparatively weak, probably having an intensity of less than 500 mm. per sec. per sec. A 100-ft. reinforced-concrete chimney 3½ ft. inside diameter at the top was found to have a period of vibration of 0.8 sec.

Some interesting observations of a chimney at Providence, R. I., are given by Dr. D. S. Jacobs, in his paper on Counterweights for Large Engines.<sup>1</sup> The stack was built on a mass of concrete

<sup>1</sup> Trans. Am. Soc. M. E., vol. 26 (1906), p. 531

which extended under the building structure. Referring to the vibration of the chimney due to the reciprocating engine, Dr. Jacobus states:

At a point near the extreme end of the foundation where the No. 1 engine was located the foundation was found to shake 0.008 in. Measurements made near the top of the chimney, which was erected to the height of about 175 ft. above the ground, showed that the maximum shake with the engine running at its ordinary speed of 50 r.p.m. was about 0.02 in. After measuring the vibration of the chimney with the engine running at its ordinary speed the engine was shut down and a marked result took place when its speed fell in harmony with the time of vibration of the chimney. When this occurred, the chimney shook to such an extent that the motion was beyond the range of the special instrument. The total movement of the pointer of the instrument was such that the chimney was shown to move more than one-eighth of an inch. In constructing the chimney the workmen had noticed that when they came to a height of about 130 ft. the vibration was much greater than it was after the chimney was built higher. This made it appear that at the height of 130 ft., at which there was the most shake, the time of the vibration of the chimney was in harmony with the number of revolutions made by the engine.

Professor Omori has also collected many data with respect to the effect of earthquakes on bridge piers.

Following the San Francisco earthquake and fire the city of San Francisco installed an elaborate high-pressure fire-fighting system, including two high-pressure salt-water pumping plants; the structures were designed to withstand earthquakes by utilizing the latest information obtainable from the San Francisco Earthquake Commission, an acceleration of 6.2 ft. per sec. per sec. being stipulated. Pumping plant No. 1 included four chimneys specified not to exceed 90 ft. in height, to minimize the earthquake risk, and measuring 64 in. inside diameter at the top. These chimneys were finally made of reinforced concrete and self-supporting.

As the writer's firm undertook to build a substantial part of this pumping plant he engaged a local engineer of prominence to make a special design of chimney to withstand earthquakes, and in the course of the next few years several other chimneys were designed in the same way. These designs followed Omori's theory, as outlined above; the bending moments due to earthquake were calculated for all sections, assuming the lateral displacement of the chimney to result from the earthquake acceleration imparted to the mass of the structure as a whole and the chimney shaft to remain vertical at all times. This theory gave a strength of chimney at the base materially greater than at the higher sections, and in view of Omori's observation of the frequency of breakage at two-thirds of the height, the reinforced amount was empirically increased at this section. No severe earthquakes have tested the accuracy of the design. Recently the writer had occasion to examine the subject further in connection with the erection of a chimney 220 ft. in height and 14 ft. in inside diameter at the top.

The chimney in question was constructed during the war time, and on account of the prohibitive price of self-supporting steel chimneys, decision was made in favor of reinforced concrete.

The writer concluded that while the chimney might have a tendency to sway somewhat about the base as an axis, the principal design should be made on the basis of accelerative rotation of the chimney about its two-thirds point, instead of a motion of accelerated translation parallel to itself, as heretofore assumed. The theory of rotation harmonizes with the observed failures of chimneys, whereas the theory of translation does not.

Considering the chimney as a rigid body and assuming the two-thirds point to be at rest and the acceleration of the earth to be known, then the angular acceleration about the two-thirds point becomes immediately known, and from the principles of moment of inertia the bending moment at different sections is easily computed. Such theory, however, would only apply if the chimney were under no strain at its base or foundation. If such rotation did exist, the chimney remaining rigid, then there must occur either a yielding of the soil under the chimney foundation, or a deflection or fracture of its base, or both. An investigation of the foundations of chimneys which had failed in the San Francisco earthquake did not lend support to this theory, and the writer finally concluded that the element of flexibility of the chimney shaft played a most important part in chimney design.

A further important consideration in chimney design is the deflection of the chimney from the base to its neutral point, assumed to be at two-thirds of its height. It is only on the assumption that a tall chimney will deflect within its elastic limit one-half the amount of the earth's vibration that its stability during a severe earthquake can be maintained without rupture.

The failure to find serious horizontal cracks near the base of the shaft or in the foundation of some large self-supporting brick chimneys can only be explained on the theory of deflection. This theory is not touched upon by Omori in any of his reports.

Fortunately it is comparatively easy to make an approximate estimate of the elastic deflection of a self-supporting chimney, but unfortunately the writer is not able to indicate the factor of safety to be applied to this deflection as compared with the earth's vibration.

The writer consulted E. P. Lewis, Professor of Physics, University of California, who submitted a statement as follows:

Since seeing you I have considered the questions raised in the memorandum which you gave me regarding the design of chimneys. As I told you, the problem seems so complex, and the factors so obscure, that I can do no more than make some suggestions regarding the physical principles involved.

In the first place, referring to Omori's view that the center of percussion of the chimney remains at rest under the impulse of an earthquake, Omori evidently makes this assumption by considering the case of an impulse at one end of the uniform rod on which no other forces act. In this case the center of percussion is a fixed axis of rotation, as is easily shown by considering that the resultant moment of momentum, due to the impulse, must vanish if taken about the point at which the impulse is applied. In the case of the uniform rod this is one-third the length of the rod from the opposite end. I think, however, that Omori's assumption is incorrect. The above applies to a body free from external forces after the application of the impulse, whereas the chimney remains fixed to its base, and the principle applies to a perfectly rigid body, which the chimney is not.

As a matter of fact, I am confident that something like this happens: The impulse comes along; an elastic wave runs up the chimney; during its first passage the center of percussion has a minimum motion; the earth movement ceases; the inertia of the chimney carries it forward until it is brought to rest by elastic reactions, which cause it to vibrate in the opposite direction, and any effect at the center of percussion vanishes. The amplitude of the motion of the top of the chimney (central segment of the vibration) probably is many times greater than that of the earth. If the earth vibrations are approximately synchronous with those of the chimney, the amplitude may become very great; if the frequency of the earth vibration is three times that of the chimney, "overtones" will appear with a nodal point one-third of its length from the top of the chimney (if of uniform section), thus adding to the possible effect due to the center of percussion.

A wooden or glass rod clamped to a massive base, which is then subjected to a shock or vibration, behaves as I have indicated above, and I am sure that a tall chimney behaves in qualitatively the same way.

I think you are right in considering that the vibratory motion of the chimney is of fundamental importance, and that account must likewise be taken of vertical displacements. Below [See Fig. 1] I sketch some of the phases of the motion of the chimney as I imagine it.

It occurs to me that especially violent effects might occur if succeeding non-periodic shocks come at such phases of the chimney vibration due to the first shock as to suddenly increase the acceleration.

I have given my ideas so far as they are clear to me. I do not speculate further because the problem is so difficult and obscure that I might easily suggest some error.

The sketches submitted by Professor Lewis are shown in Fig. 1. At *a* is shown a vibrating rod, fixed at the base, in its initial position; at *b* the effect of the center of percussion; at *c* the effect when the center of percussion vanishes; and at *d* the effect of a three-to-one overtone.

The ordinary chimney having much less flexibility than the experimental rod considered by Professor Lewis, it is the writer's opinion that the extreme effects which Professor Lewis mentions would not be experienced by a chimney with intensity of shock equal to that of the San Francisco earthquake.

In completing the design of the chimney in question, it was necessary for the writer to make certain assumptions, as follows:

1. That the minimum strength at any section must be equal, of course, to that required to withstand wind pressure; that an earthquake would not occur at a time of the hurricane wind velocity for which the chimney is designed; and that the addition of these forces would be unnecessarily conservative.

# Electric Power Supply of Southern Textile Mills

By J. E. SIRRINE,<sup>1</sup> GREENVILLE, S. C.

**I**N that section of the South comprising the Carolinas, Georgia, Alabama, and Tennessee there are 840 cotton mills manufacturing cloth and yarn and 310 cotton knitting mills. Fifty-seven per cent of these plants are operating on purchased electric power and consume approximately 700,000,000 kw-hr. annually. In twenty years the number of mills has increased 311 per cent; and in the past ten years alone this increase has been 43 per cent. The present annual consumption of cotton is now 3,100,000 bales, or approximately 30 per cent of the entire amount grown in America.

The earlier textile mills were naturally located at water-power sites, and they accordingly suffered from lack of transportation facilities, access to labor markets and damage by flood. Transmission in these mills was entirely mechanical. The development of steam power made possible the more advantageous placement of the mills on transportation routes and in communities capable of supplying labor. These steam-driven mills were at first developed with mechanical transmission, and this equipment was developed to a high degree of perfection along well standardized lines.

The development of alternating current and the commercial production of the induction motor provided a new type of transmission which was quickly adopted, and complete mills were equipped throughout with these motors in the early 90's. It is interesting to note that some of the original motors are still in successful operation and giving first-class service.

The first textile mill to use transmitted electric power was probably the Columbia Duck Mill, in Columbia, S. C. At this plant the power was simply transmitted a few hundred feet from the generating plant on the power canal to the mill on the

The hydraulic generating plants have an aggregate capacity of 500,000 kva., and in connection with these plants are operated steam auxiliary stations with a capacity of 150,000 kva., making a total developed capacity of 650,000 kva. The power companies own undeveloped water power sites with an aggregate probable capacity of 450,000 hp.

The hydroelectric developments utilize moderate heads, ranging from 12 to 580 ft. and averaging 40 to 60 ft. Storage reservoirs are being built on some of the streams to conserve the seasonal flow. In several cases a number of plants are built on the same stream and successive use of the water is obtained.

The steam auxiliary plants are now built with first-class construction throughout, and employ the best equipment and mechanical saving devices. In some of the earlier plants the mistake was made of depending on cheap and ample labor, factors which no longer exist.

A TYPICAL PICKER ROOM WITH INDIVIDUAL MOTOR DRIVE

The main transmission lines are usually designed for operation at 60,000 or 110,000 volts, and these lines are carried on steel towers. As a rule, twin circuits are used on the more important lines. For branch lines, voltages of 10,000, 22,000 and 40,000 are generally employed, and the circuits supported on wooden poles. All the standard systems are 60-cycle, 3-phase, so that interconnection and exchange of power between the companies is readily carried out.

The general map of the territory, page 162, shows the principal trunk transmission lines. It should be noted that there is a continuous trunk which can be interconnected from Goldsboro in the eastern part of North Carolina to Nashville in middle Tennessee, a distance by air line of 500 miles and by transmission line of 720 miles. This is equivalent to a transmission line between Bangor, Maine, and Philadelphia, which would serve the industrial territory lying between these cities.

There are two classes of electric power sold in the territory, one known as primary power, which is guaranteed for continuous supply, barring accidents; the other, known as secondary power, is furnished only when there is sufficient water in the streams to generate it, and when the power company cuts off this class of power, the mill plants are compelled to generate this power locally with prime movers.

The cotton mills give a steady all-day load which is highly desirable from the central-station standpoint. The maximum peak occurs at the starting hour in the morning when the machinery is cold. This peak is about 10 per cent above normal. The rest of the day the load is practically uniform.

At the mills the transmitted power is usually stepped down to 550 or 220 volts, and at these lower voltages is distributed throughout the plant.

(Continued on page 203)

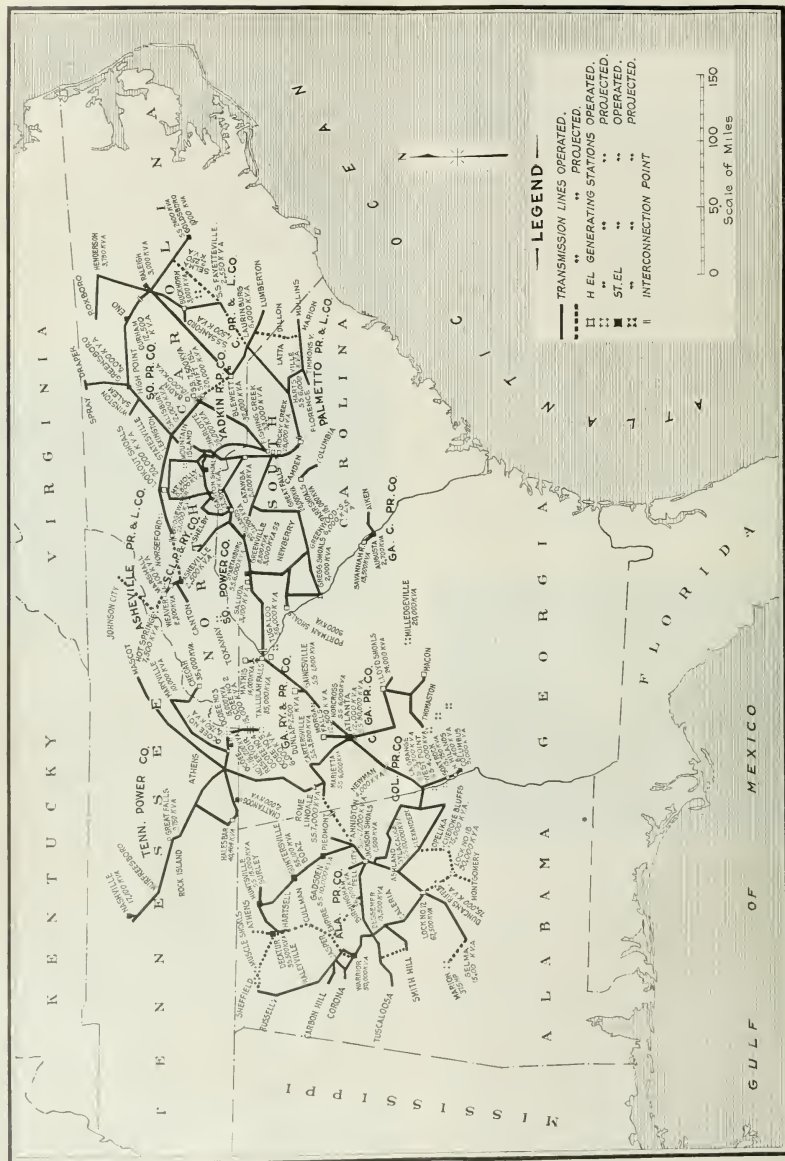

TYPICAL INSTALLATION OF SPINNING FRAMES EQUIPPED WITH INDIVIDUAL MOTORS

bill. Following this came the Pelzer Manufacturing Company's installation where power was transmitted for approximately four miles at 3,500 volts and stepped down at the mill to 230 volts. These were both isolated plants. Probably the first commercial generating and transmitting project was the Portman Shoals plant of the Anderson Water, Light & Power Company, at Anderson, S. C. In this plant the power was generated at 10,000 volts and transmitted at this voltage to the Orr and other mills in the city of Anderson, S. C.

As the advantages of electric-motor drive became more generally recognized other companies were developed for the generation and transmission of electric power, and there are now approximately twelve large companies in the territory, with an interlocked network of transmission lines practically covering it.

# The Proper Balancing of Fuel, Lubricant and Motor

A Study of the Dilution of Lubricating Oils in Aeronautic and Automobile Engines by the Gasoline Mixture and the Resulting Losses of Fuel, Power and Lubricant

By WILLIAM F. PARISH, CHICAGO, ILL.

*Dilution of motor lubricating oil has always existed; this condition is caused by the gasoline mixture escaping past the piston rings, with a possible secondary cause—drainage of the diluted oil from the cylinder walls.*

*In the earlier years of highly volatile gasoline the gas escaping past the piston rings did not enter extensively into the body of the lubricating oil, and while mechanical losses of fuel took place in all four-cycle engines, this loss did not reflect itself in a problem of dilution. In the past few years, however, due to the heavy end components of the fuel, a larger amount after passing the rings, upon condensation, remained in the lubricating oil, thus creating a condition of dilution.*

*Not until the period of high-end-point gasoline did the matter of fuel loss become apparent, and then only in proportion to the amount held in solution in the lubricating oil. This condition, which has become especially accentuated in the past three or four years, has resulted in undue wear upon the engine parts as well as affecting the use of fuel, lubricant, and power.*

*The purpose of this paper is to call attention to this underlying trend in the situation and to suggest a method of application of motor oils to correct some of the present faults. It is felt that a true solution can be reached only in changes in mechanical equipment of the engine, and a plea is made for better engine design and greater economy in the use of gasoline and lubricating oils.*

**D**URING 1911, in conducting research work in connection with the use of various fuels and lubricant on a four-cylinder automotive engine and in examining the lubricating oils before and after use, it was noticed that the oil drawn from the crankcase after use had undergone a considerable physical change, the most noticeable thing being that the viscosity of the oil had been lowered during use until it was only one-half or one-quarter as much as the viscosity of the new oil. The flash or ignition point of the used oil was only a third of the original, in some cases being lowered from 470 deg. to 150 deg. Fahr. Other just as remarkable changes had taken place in the gravity and cold test of the oil.

The automotive engineers who made the tests stated they had always noted a similar condition in the case of racing cars where, after a hard race, the oil drawn from the engine was as thin as water, even when it was cold.

Technical records were searched for similar information. The only reference regarding the lowering of the flash point and lowering of the body of the oil in automotive engines was found in an English paper, which stated that this condition had been noted but that no solution had been found. The matter was then taken up with the most prominent automotive manufacturers, the condition explained to them, and they were asked if they had noticed the changes that had taken place in the lubricant in their engines. Practically the only answer was that the oil in these engines had worn out and become thin.

An article prepared by the author and published in June, 1912, ascribed the changed condition of the motor lubricant to the leakage of gasoline vapor during the compression stroke, recondensation of this vapor in the crankcase, absorption by the lubricant, and to a probable slight leakage down the walls of the cylinder of unconsumed heavy portions of the fuel which had mingled with the lubricant, producing a similar effect. This condition has always existed, but has become more pronounced and better understood during the last two years.

The tremendous growth of the automotive industry during the past few years, with the consequent burden placed upon the oil industry of producing the vast amount of fuel required, has brought about an unbalanced condition. Because of the enormous increase in consumption of gasoline—from 15,000,000 bbl. in 1910 to approximately 95,000,000 bbl. in 1919—the petroleum industry has been able to meet demands only by the manufacture of a less volatile fuel.

Navy Department specifications show that during the past few years automotive fuels have been gradually getting heavier, approximately from 360 deg. Fahr. end point in 1916 to 428 deg. Fahr. end point in 1919. (The end point is the temperature at which the final part of the fuel vaporizes.)

There is ample evidence that this increase in the use of heavy fuels will continue and it follows, therefore, that gas-engine designers must so design their engines as to consume successfully this less volatile product.

## LUBRICATION TESTS ON AN AERONAUTIC ENGINE

During the war, before writing specifications for lubricating oils and fuels for aeronautic and other internal-combustion engines, it was necessary to make a complete study of this subject in order that the fuel and lubricants could be so balanced that their combination in the engine would give the necessary lubricating results. These main tests resulted in the specifications for Liberty Aero Oil, and had much to do with specifications for aviation gasoline, including domestic, export and fighting grades. A Hall-Scott aeronautic engine, Type A-7-A, four-cylinder, 100 hp., was used for the special fuel tests of the series. This engine was operated under ideal test conditions, working with the same lubricant but with different fuels. Two of these fuels were made especially for the test and were distilled from the same crude.

The first fuel tested was made after the German specifications for aviation gasoline, and had a gravity of 75.2 deg. B., an initial boiling point of 110 deg. Fahr. and a final boiling point of 230 deg. Fahr.

The second fuel tested was made after the French specifications and had a gravity of 63.6 deg. B., an initial boiling point of 140 deg. Fahr., and a final boiling point of 292 deg. Fahr.

The third fuel complied with regular Navy specifications for motor-boat fuel under contract for the year 1917 and had a gravity of 61.3 deg. B., an initial boiling point of 135 deg. Fahr. and a final boiling point of 385 deg. Fahr. To this fuel a so-called gasoline energizer was added. This produced a fuel which, while it had an initial boiling point of 135 deg. Fahr., had an end point of 422 deg. Fahr., which in its last distillation range would be equivalent to the present-day commercial gasoline.

The method of conducting the tests was to run the engine continuously for five hours under test conditions, every observation in connection with the operation being recorded. At the end of every hour samples of lubricating oil were drained from the lubrication system of the engine and the same amount of new oil replaced. These samples were examined by a corps of very efficient oil chemists working at the Bureau of Standards, at the oil laboratory in Washington Navy Yard, at two commercial laboratories, and at the Naval Experiment Station at Annapolis.

The effect of the four different classes of fuel upon the same lubricant is clearly registered in the charts in Figs. 1 and 2. The lightest or most volatile fuel shown in test No. 3 caused a lowering of the viscosity of the lubricating oil during the first hour

<sup>1</sup> Sinclair Ref. Co. Mem. Am. Soc. M. E.

Presented at a meeting of the Chicago Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, January 23, 1920.

of 62 sec. (Saybolt universal viscosimeter). The oil, however, recovered its body, and at the end of the fifth hour was 87 sec. above its original viscosity or body.

In test No. 2, Fig. 1, with a slightly heavier fuel, there was a reduction in the body of the oil of 114 sec. during the first hour. The oil, however, recovered after the first hour, and at the end of the fifth hour had a viscosity of 55 sec. above its original body.

Test No. 1, with a semi-commercial fuel, showed a drop in the body of the oil in two hours of 304 sec., with a slight recovery during the balance of the test. There was a total reduction of 136 sec. at the end of five hours from the body of the original oil.

FIG. 1 CURVES OF GASOLINE DISTILLATION AND OIL VISCOSITY SHOWING CHANGE IN LUBRICATING OIL WHILE WORKING IN ENGINE

In test No. 4, Fig. 2, with the high-end-point gasoline, there was a drop in two hours of 250 sec. in the body of the lubricant, only a slight recovery and a total drop at the end of five hours of 213 sec. from the original body of the oil.

The sample taken at the end of the five-hour period of each one of these tests was tested in a distillation flask and the amount of heavy end of the gasoline recovered varied from 0.5 per cent to 1.2 per cent as indicated on the chart in Fig. 3. All of the physical characteristics of the oil, such as gravity, flash, fire, viscosity, pour test, acidity, carbon content, showed a considerable change as indicated in Fig. 5.

In Fig. 5 carbon conditions are indicated which are especially interesting as showing the laboratory variations on four samples of the same new oil when taken by the Conradson and the Waters carbon test. Particularly interesting is the sample by weight and residue, test No. A4, where practically commercial gasoline was being used in the engine. This heavier carbon residue or deposit found in the used oil indicates the increased amount of carbon being formed in the engine while using the heavier fuel.

The results of the above tests indicate quite clearly that dilution exists with even the most volatile fuel, but only during certain periods of the operation of the engine and under certain fixed

conditions. With the lightest volatile fuel, which would also be the case with the engine operating on producer, natural or furnace gas (some figures on this are given later), the tendency of the lubricating oil would be to build up in body, the same as in any other class of lubrication work where the lubricant does not come in contact with lighter hydrocarbons or lighter volatile products that can be combined with it. These tests also indicate quite clearly that the heavier the end point of the fuel, the greater is the effect of dilution and the more permanent is its character.

It must be borne in mind that in these experiments the aeronautic engine was operated with an exceedingly heavy lubri-

FIG. 2 CURVES OF GASOLINE DISTILLATION AND OIL VISCOSITY SHOWING CHANGE IN LUBRICATING OIL WHILE WORKING IN ENGINE

cating oil, such as these engines require, and that carburetor and magneto adjustments were attended to by experts; that the engine was placed in perfect condition for each test and operated continuously without stopping, at high speed, for the entire five hours of the test.

#### LUBRICATION TESTS ON AUTOMOBILE ENGINES

The following data were secured from the examination of lubrication conditions of a considerable number of cars and trucks during December, 1919, using commercial gasoline and lubricants as purchased in the Chicago market. In some cases the cars were new as received from the manufacturer, and in other cases old, or old and repaired.

In preparation for the tests, the motors were thoroughly cleaned and the crankcases filled with the oil to be tested. The oils so used covered a range of commercial medium and heavy grades as indicated by Government specifications for motor oils. The cars were allowed to operate in their regular business for periods of ten days, during which time no particular care was given them other than ordinarily given commercial vehicles, but at the end of each two-day period an eight-ounce sample was

drawn from each crankcase and eight ounces of the grade of oil used on that particular motor was put in whenever additional oil was necessary. The samples were examined for dilution by measuring all the product that could be distilled from the sample of oil under 500 deg. Fahr. The viscosity (Saybolt) of the sample before removal of the diluent was taken at 100 deg. Fahr. The ash test was made in the Conradson carbon apparatus, and after the carbon had been determined a gas flame was used for burning the carbon out of the dish. The ash that remained was then weighed and the percentage taken of the whole sample. This ash was made up of iron, iron oxide and silica. The results of the tests are given in Figs. 6, 7 and 8.

Fig. 6 shows the results on a 3½-ton Diamond "T" truck. This was a new car which had not been run previous to this test. Viscosity at the end of ten days was reduced from 345 to 100 sec. Dilution the tenth day amounted to 19 per cent and ash to 1.62 per cent.

Fig. 7 shows the results on a 5-ton Pierce-Arrow truck which had run 5205 miles. On July 4, 1919, this motor was completely overhauled, new piston rings being fitted. Viscosity dropped from 358 to 90 sec. during the first six days, then recovered to 184 sec. at the end of ten days. Dilution in the case of this truck seemed to be very dependent upon weather conditions; at the end of the six-day period there was 20.6 per cent of dilution, which was reduced to 8 per cent at the end of the ten-day period.

Fig. 8 shows the results on a 3½-ton Packard truck which had run 12,551 miles. Overhauled May 5, 1919: new rings fitted. (Note: This truck did not go out of the garage for the first two days. Engine, however, was run during this time for a period that would be equivalent to five miles' operation.) The viscosity held practically constant for the first two days when the truck was not operating in the open. After the second day there was a drop in viscosity to 43 sec. Dilution at the end of the tenth day was 26.5 per cent.

### CAUSE OF DILUTION

With the present-day fuel and the present-day automotive engine, all lubricants change considerably in body within a very

FIG. 3 RESULTS OF DISTILLATION TEST OF OIL AFTER FIVE-HOUR RUN

short operating period, this new body being the result of dilution and the dilution coming from the heavy end of the fuel.

The amount of dilution is influenced, to a great extent, by the temperature of the surrounding air, the reason being that the colder the engine, the greater the amount of fuel the oil will absorb and hold. Conversely, the hotter the air or lubricating oil in the engine, the less will be the amount of fuel held in dilution, as all the fuel can be distilled off at high-temperature.

In order to see if any of the dilution of a motor oil could be caused by decomposition or cracking of the oil by being thrown against hot surfaces, tests were made by the author with a com-

mercial car operated by pure benzol. From 4 to 8 per cent of benzol was distilled from the motor oil after 100-mile runs. After the benzol had been removed the oil possessed all of its original characteristics. Benzol, wherever found, can be determined as such by the chemist. These benzol tests determined satisfactorily that dilution was being caused by the fuel, although an odor of burned oil indicated some degree of decomposition.

The conclusions drawn from the above test with benzol are confirmed by the results of a test on a Nash six-cylinder engine operated with city gas for 10 hr. The original viscosity of the oil at 100 deg. Fahr. was 205 sec.; after ten hours' operation the viscosity had increased to 255 sec., the flash and fire points remaining practically the same, showing that there had been no change in the oil caused by cracking and reabsorption of the lighter products, but that the absence of lighter products allowed the oil to become heavier in body.

Dilution is caused mainly by leakage past the piston rings during the compression stroke. There is a secondary leakage

FIG. 4 RESULTS OF TESTS SHOWING VARIATION OF CARBON CONDITIONS IN FOUR SAMPLES OF NEW OIL

caused during the suction stroke, where there is a partial separation of heavy ends of the fuel from the gas entering the cylinder and absorption by the film of oil on the cylinder walls, causing some drainage on the lower exposed surfaces during the compression stroke. It is doubtful if any drainage or leakage takes place during the exhaust stroke or during the power stroke. If we assume that the losses take place during the admission and compression strokes, we are dealing with one-half of the operating period of the engine, and that will give all the opportunity necessary for the effects that have been noticed to take place.

Leakage of the gasoline or gasoline mixture is influenced by the following mechanical or operation conditions:

- 1 Piston clearance
- 2 Richness of mixture
- 3 Improper ignition
- 4 Operating temperature of motor affected by weather
- 5 Body of lubricant or thickness of film on walls of cylinders
- 6 Condition of cylinder walls
- 7 Condition of piston rings as affecting their all-around fit in the grooves and against the cylinder walls
- 8 Intermittent operation
- 9 Priming and using the choke when engine is cold in starting
- 10 Choking when overloading
- 11 Character of fuel
- 12 Carburetor out of adjustment
- 13 Vacuum system out of adjustment.

# LOSSES CAUSED BY DILUTION

These losses are of four kinds:

- 1 Loss of fuel
- 2 Loss of lubricant.
3. Loss of power
- 4 Wear of all parts.

FIG. 5 CHART OF OIL ANALYSES AND CARBON CONTENT; ENGINE, HALL-SCOTT, TYPE A7A, No. 3012, 100 Hp.

## LOSS OF FUEL

This loss is not entirely due to the heavy end of the fuel or to the present heavy character of the fuel, as, irrespective of the nature of fuel, whether light and volatile or heavy, there will be a fuel loss during the compression stroke in a four-cycle engine. In the case of heavy-end fuel this loss is reflected to a magnified extent in the dilution effect upon the lubricating oil. In the case of a very much lighter fuel, say one of 72 deg. B., the loss by the rings during the compression stroke would be just as pronounced in percentage of the amount taken into the cylinder, supposing the sealing effect of the lubricant on the piston rings to be always the same, but the effect would not be as noticeable, due to the lubricant's inability to absorb and hold the lighter fuel as a diluent at operating temperatures.

The amount of fuel lost in this manner is in no way represented by the amount of dilution found in motor oils, as there is a limited point of saturation of a motor oil dependent upon the condition under which it is operating. The losses which constantly occur are disposed of by the engine in some other way than by being entirely absorbed by the lubricant.

The loss of fuel by leakage means that all the fuel placed in the cylinder is not converted into power.

## LOSS OF AND THROUGH THE LUBRICANT

The first effect of dilution is upon the viscosity or body of the lubricating oil, reducing this body to a point where it cannot be considered to be an efficient lubricant for a motor. This causes three conditions, which can be stated as:

- 1 Loss of lubricant
- 2 Loss of power
- 3 Wear of the machine

The first effect is the wastefulness of the lubricant, as the entire loss of lubricating oil in an internal-combustion engine is caused

by the lubricant creeping up the cylinder walls, mainly during the first cycle or admission stroke, and being later consumed in the combustion chamber. The lighter the oil is in body, the greater will be this loss. Further, there is another loss that is due to the present condition of dilution and the attempts made to offset it, and that is by the removal of lubricating oil from the engine at periods of from 300 to 800 miles, instead of the former periods of double this mileage, this mixture being thrown away.

## LOSS OF POWER

The basic rule in lubrication is illustrated best by considering the power necessary to operate a machine composed of a number of bearings. If the machine is lubricated perfectly with oil of the proper viscosity, the power will be at a minimum and speed at a maximum, and there should be practically no wear on the bearings. If, however, an oil of double or treble the viscosity is used as a lubricant, the power necessary to move the machine at the same speed will have to be materially increased, due entirely to the fluid friction of the lubricant itself. Under this condition there will be practically no wear, as the surfaces will be kept well apart. Attempting to lubricate the same machine with an oil that is entirely too light or thin for the work will also require the development of practically as much, or even more, power than in the case of the extra heavy oil, the resistance being due to metallic or solid friction, one of the results of which is, of course, abrasion with constant changing of the surfaces.

FIG. 6 VISCOSITY AND DILUTION TESTS OF OIL, 3 1/2-TON DIAMOND "T" TRUCK

The general rule as applicable to automotive engines when considering the dilution problem is well illustrated by a test on a tractor engine using kerosene for fuel where the output at the start of the test was 28 b.h.p., gradually dropping to 24.5 b.h.p. in eight hours, indicating a considerable increase in the frictional

horsepower. The viscosity (Saybolt) of the oil at 100 deg. Fahr. changed from 300 sec. at the start to 75 sec. at the finish of the test, at which time there was 36 per cent of dilution in the oil. Temperature of oil in crankcase increased from 98 deg. Fahr. at start to 135 deg. Fahr. at end of run.

A lubricant actually working in a motor should have a body at least equal to that possessed by a new heavy spindle oil (130 sec. viscosity at 100 deg. Fahr.) and an oil of such light body must be used in a forced-feed system where the pressure and constant flow of the oil will make up for its lack of thickness of lubricating film.

As a matter of fact, under present conditions of operation most motor oils when in an engine, in the winter especially, are much lighter than a lubrication engineer would ever think of applying to the lightest piece of machinery he would be called upon to lubricate, which is a light spindle in a textile mill. A description of these spindles will permit comparisons to be made. They rotate at about 10,000 r.p.m., and the side pull or pressure averages 2 lb. The pressure on the bearing side will not be above 10 lb. per sq. in. The high rotation speed of the spindle tends to keep it away from the bearing surface and keep it in the center of the bolster. About one ounce of oil is placed in the base of the spindle, and this amount is added to every 15 to 45 days. It has been proved by the most careful experiments that oil that has a viscosity (Saybolt) of less than 60 sec. at 100 deg. Fahr. will allow these spindles to wear perceptibly in a month's time. The oil remaining in the spindle base will become black and contain a very considerable proportion of iron and iron oxide. Further, the same spindles when lubricated with oil of from 70 to 80 sec. viscosity do not wear, due to the fact that the oil is of sufficient body to keep the surfaces apart.

FIG. 7 VISCOSITY AND DILUTION TEST OF OIL, 5-TON PIERCE-ARROW TRUCK

Therefore, the result of the lubrication of an automotive engine with a mixture of lubricating oil and heavy ends of the gasoline having a viscosity below that required for a textile spindle can only result in excessive wear, and this is shown by the ash remaining from the complete distillation of the sample of mixture taken from the motor.

## WEAR OF MACHINE

The effect of poor lubrication is indicated to some extent by the readings of ash. These readings were taken on each sample and represent the total amount of ash in that particular sample. The ash is made up of oxide of iron, other metal, and of silica,

FIG. 8 VISCOSITY AND DILUTION TESTS OF OIL, 3 1/2-TON PACKARD TRUCK

the iron and other metal being from natural or unnatural wear of the engine, the oxide of iron coming from the water that has been in contact with the metal, and the silica coming from road dust, though at the time of the year this particular test was made the streets were well covered with snow and but little road dust could be expected to enter the engine through the carburetor or breather holes.

The wear of the machine is reflected in repair bills, in the necessity for reboring cylinders and refitting rings when an engine becomes noisy and when compression is lost.

All of these matters are so well known as not to need explanation. They are largely the result of wear caused by the present unbalanced condition of fuel, lubricant and engine.

## CONCLUSION AND RECOMMENDATIONS

As engineers we are now faced with a very definite problem. It is necessary to reconsider the entire problem of the internal-combustion engine on the basis of present-day fuel and its effect upon the lubricant. There is but little more that the oil industry can do in regard to the fuel situation. Considerable can be done in regard to the application of motor oil; that is, the selection of motor oil for these engines upon some other basis than has generally been prevalent in the past whereby a motor of any one manufacturer was supposed to be properly suited by a certain grade of lubricant for its entire life irrespective of its physical condition. Modern lubrication engineering can, to a very considerable extent, rectify some of the damage done by this old system of selecting lubricants, basing the selection upon more scientific or practical grounds, taking into consideration all of the factors which surround the problem.

The entire problem of lubricant, fuel and engine conservation can only be solved by the automotive engineer or designing mechanical engineer providing means and methods whereby the fuel

### ABRASIVES

**NEW ALUMINOUS ABRASIVE.** Otis Hutchins. Description of an abrasive material known as Aloxite AA, developed by the Carborundum Company. The main application of the new abrasive is expected to be for the grinding of reamers, cutters and small tools and also for certain kinds of cylindrical grinding.

The chief structural characteristic of the new abrasive is the large size of the alumina crystals found therein.

The importance of this factor lies in the following: When the alumina crystals in the abrasive material are small a rupture of the grain may mean a tearing away of a few small crystals without fracture. When, however, the crystals are large and a rupture occurs in an abrasive grain it means that the crystal of alumina has been fractured and that new sharp cutting points have been produced. In this way, during the process of grinding, there is a breaking down of the abrasive grains in the wheel and the character of the new cutting edges is such as to facilitate an easy removal of the ground material. (*American Machinist*, vol. 52, no. 3, Jan. 15, 1920, pp. 113-114, 3 figs., d)

### DRYING

#### Drying Theory, Most Economical Temperatures, Graphic Determination of Weight of Moist Air

**CONTRIBUTION TO THE THEORY OF DRYING,** E. Hoehn. Discussion of the most economical temperature and most economical degree of saturation for the air at the outlet from the drying chambers; discussion of influence of air pressure; and graphical methods for the solution of problems in connection with processes of drying.

**Most Economical Temperatures.** The fact that the highest possible temperature of air is the most economical in drying is well known. This is due to the fact that the ability of air to hold moisture rises very much more rapidly than does its temperature.

A good deal less information is available, however, as to the temperature at which the air should leave the drying chamber. (Such air is referred to in what follows as "exhaust air.") As regards this latter, the impression seems to prevail that it is of advantage to have such air leave the drying chamber at the lowest possible temperature and the highest possible degree of saturation. The assumption as regards the necessity of employing a high degree of saturation in order to insure the economic operation of the drying process is correct, but the assumption as to the necessity of keeping the air at a low temperature rests on an erroneous conception of the character of the process. In order

to clear up this matter, the author investigates how many grams of water each heat unit (kg.-calorie) contained in the air (considered as a mixture of air and water vapor) can carry away.

The weight of 1 cu. m. of moist air is composed of  $\phi G_d$  kg. of water and  $0.465 \frac{p - \phi p_d}{273 + t}$  kg. of dry air. In this formula  $\phi$  is the degree of saturation in per cent;  $G_d$  the weight in kg. of 1 cu. m. of saturated steam at the temperature  $t$ ;  $p$  the barometric pressure of the air-water vapor mixture in mm. of mercury;  $p_d$  the steam pressure at the temperature  $t$  (really the partial pressure of the steam content in the mixture) in mm. of mercury. Further,  $p$  is the partial pressure of the air equal to  $p - \phi p_d$  in mm. of mercury.

In this formula  $G_d$  and  $p_d$  for a given temperature can be found in steam tables; the degree of saturation  $\phi$  can be measured by means of a hygrometer, or more precisely by a psychrometer. The heat content of 1 cu. m. of mixture at temperature  $t$  (or 1 cu. m. of the mixture of the weight given above) is equal to

$$J = \phi G_d i + 0.465 \frac{p - \phi p_d}{273 + t} 0.24 t$$

where  $i$  is the heat content of 1 kg. of steam at temperature  $t$ ; the coefficient 0.24 is the specific heat  $c_p$  of 1 kg. of air at constant pressure (all values in metric units).

It is clear from the above that the weight of water vapor corresponding to one heat-unit (kg.-calorie) content as part of the total heat content in 1 cu. m. of moist air is  $\phi G_d / J$ . It is desirable to plot this fraction as a function of temperature  $t$  in order to see what would be its maximum and minimum values. To do this the author, instead of resorting to the complicated analytical treatment of the problem, simply computes the values of the numerator and denominator of the fraction and plots the quotients as coordinates with the temperatures as abscissae. This is all the easier as both the parts of the fraction can be read off from existing tables, and as it does not matter whether the values are taken for the case of 1 cu. m. of moist air or for such a volume that the dry air contained therein would weigh 1 kg. (The tables are computed for the latter case.) If this computation be carried out for the barometric pressure of 720 mm. of mercury the curves of Fig. 1 are obtained.

This gives the desired picture showing the ability of the air to take up moisture as measured by heat content of the air. It appears that the curves come down at about 15 deg. cent. and then rise again, the greatest rise lying between 30 and 70 deg. Hence, the least favorable temperatures for drying purposes are located in the region of 15 deg. where the curves are at their lowermost points. In this region 1 kg.-calorie of heat contained in the air will enable the latter to carry off the least amount of water.

Attention is called also to the fact that Fig. 1 justifies the assumption that it is just at the average temperatures prevailing

in the summer that the greatest consumption of heat is required by nature for the purpose of humidification of the air. From this point on, that is, from about 20 deg. cent., the absorption of moisture in drying becomes more economical the higher the temperature of the exhaust air is carried, assuming, of course, equal degrees of saturation. In the case of perfectly dried air ( $\phi = 0$  per cent) the ordinate is zero and the curve reaches the axis of abscissae. The highest location of the curves is at about 1.56 to 1.54 grams per large calorie. Each curve ends at its highest point, which latter corresponds to a definite state of mixture which is determined in the following manner. When in the weight

$$G = \phi G_d + 0.465 \frac{p - \phi p_d}{273 + t}$$

a partial steam pressure  $p_d$  reaches the level of the total pressure  $p$ , that is, when  $\phi p_d = p$ , and hence the partial pressure of the air  $p_a = p - \phi p_d = 0$ , the second member of the right-hand side disappears; in other words, air disappears from the mixture and

FIG. 1 CURVES OF MOISTURE CONTENT IN GRAMS AT VARIOUS DEGREES OF SATURATION AS FUNCTION OF TEMPERATURE  $t$  WHICH CAN BE CARRIED OVER BY 1 C.C.M. OF MOIST AIR FOR EACH LARGE CALORIE OF THE HEAT CONTENT OF THE AIR

only steam is present. If, at the same time,  $\phi$  becomes equal to 100 per cent, we are dealing with a state in which the dewpoint is reached and this can occur only where the steam pressure is equal to the total pressure. This point may be called the limit dewpoint. When  $\phi < 1$  we can find such a steam pressure  $p_d$  on the basis of the temperature  $t$ , so that  $\phi p_d = p$ . Thus, with  $\phi = 0.5$  the steam pressure  $p_d$  is 1520 mm. of mercury, at which at the barometric pressure of 760 mm. the steam drives the air entirely out of the mixture. This can happen at  $t = 120.6$  deg. cent. It is obvious that the consumption of heat in the heat carrier is at its minimum when the heat carrier consists entirely of steam and no air is present. In Fig. 1 the curve  $\phi = 100$  per cent at its interpolated continuation constitutes the upper limit of the region within which drying is at all possible. Fig. 1 gives also valuable information as to what degree of saturation is most economical. When very high degrees of saturation, such as 80 or 90 per cent, have been reached a further rise of saturation does not appear to improve matters very much. On the other hand, in the lower regions of saturation, such as 50 or 60 per cent, the amount of water carried away increases more rapidly with the heat consumption. On the whole, the curves of Fig. 1 would tend to indicate that the economy of the process is the same whether we operated with moist air of, say, 40 per cent saturation at 78 deg., or 60 per cent saturation at 63 deg., or 80 per cent saturation at 54 deg., or perfect saturation at 46 deg.; in all of these cases we have to expend 1 kg.-calorie in order to carry off

1.3 grams of water. The conditions most easily attainable mechanically and still satisfactory from an economic point of view would lie, as far as temperature is concerned, between 60 to 80 deg. cent. and 60 to 80 per cent of saturation, in which case we expend roughly 1 kg.-calorie of heat to take care of 1.4 grams of water, which means an expenditure of 0.7 kg.-calorie of heat for one gram of water, or 700 kg.-calories of heat for 1 kg. of water.

This is very nearly the same as the heat necessary to evaporate 1 kg. of water at atmospheric pressure, which is 640 kg.-calories. Under this condition the efficiency of drying is close to 90 per cent.

At 100 deg. cent. and  $\phi = 100$  per cent, that is, when the air is entirely driven out of the mixture by the steam and the limit dew-

above, the weight of 1 cu. m. of moist air in kg. may be calculated from

$$K_t = \frac{0.465}{273 + t}$$

$$G = \phi G_d + \frac{0.465}{273 + t} (p - \phi p_d)$$

We can represent these equations graphically by taking the first factor from the steam table and multiplying it by the value of the degree of saturation. This is done in Fig. 2 where the weight of steam  $\phi G_d$  is plotted as ordinates from the upper axis of abscissa downward, while the temperatures are plotted as abscissae.

As regards the second factor, both parts of it are reproduced graphically;  $\frac{0.465}{273 + t} = K_t$  is at zero deg. Fahr. = 0.0017015 and at 100 deg., 0.0012454. Any scale may be selected to plot this curve and it will be found in Fig. 2 as a practically straight line on the bottom.

At partial air pressure  $p_i = p - \phi p_d$ , the maximum barometric pressure  $p = 760$  mm. is selected as the length of the highest ordinate and measured from the bottom upward;  $p_d$ , which is the steam pressure at complete saturation or a function of the dew-point curve, is transferred into the diagram from the steam tables and measured from the bottom upward;  $\phi p_d$ , which is the partial pressure of steam dependent on the degree of saturation, is to be found on one of the curves located below the dewpoint curve ( $\phi = 100$  per cent).

Hence, the partial air pressure  $p - \phi p_d$  is represented by the section of the ordinate located between the curve of total pressure  $p$  (for example, barometric pressure of 720 mm.) and the corresponding curve  $\phi p_d$ , but the value of  $p - \phi p_d$  is multiplied by the coefficient  $K_t$  corresponding to the given temperature and the product, which is  $K_t(p - \phi p_d)$ , is to be added to the length of the ordinate  $\phi G_d$  located on the same ordinate  $t$  and measured from top downward.

The curves in Fig. 2 may be therefore used for a rapid computation of the weight of moist air for all cases and for barometric pressures up to 760 mm. pressure in C. G. S. units.

Other parts of the article may be abstracted at a later date. (*Beitrag zur Theorie des Trockens und Dörrens*, E. Höhn, *Zeitschrift des Vereines deutscher Ingenieure*, vol. 63, no. 35, August 30, 1919, pp. 821-826, 5 figs., tp)

## ENGINEERING MATERIALS (See also Abrasives)

A PECULIAR TYPE OF INTERCRYSTALLINE BRITTLENESS OF COPPER, Henry S. Rawdon and S. C. Langdon. When copper is heated in a molten bath of sodium chloride for the purpose of cleaning and softening, it has been noticed that the copper becomes embrittled. Under these conditions the copper is more or less in contact with iron or steel, either from a stirring rod, forceps for handling the piece or the pot used to contain the salt, and a "galvanic couple" with the copper serving as cathode would be formed.

Experiments were made with small rods of copper and mild steel which were made either anode or cathode in a bath of molten salt and with an e.m.f. of approximately six volts. The brittleness of the copper rods was compared with untreated material by bending the specimens back and forth with one end firmly clamped.

The copper rod which was an anode was as tough and soft as the original and required practically the same number of bends to cause it to fracture. The cathode copper was found to be very brittle.

Microscopic examination showed the anode copper to be perceptibly smoother on the surface than the original material; the structure was that of annealed copper. In the cathode copper rod the crystalline boundaries on the surface are well defined, and the intercrystalline boundaries for an appreciable depth within the metal are wider.

The probable explanation of embrittlement of the copper when it is made the cathode is that an appreciable amount of metallic

sodium is formed by the electrolysis which immediately alloys with the copper, the attack being selective toward the grain boundaries rather than forming an alloy layer of uniform thickness upon the outside. (Abstract of *Technologic Paper of the Bureau of Standards*, no. 158, e)

## Endurance Diagram as Criterion of Fatigue of Metals

FATIGUE OF METALS UNDER REPEATED STRESS, Herbert F. Moore. Discussion of fatigue failure of metals; criticism of some methods of determining it and discussion of a proposed standard method of the determination of fatigue resistance, namely, by means of an endurance diagram.

The author does not believe that elastic-limit figures help in any reliable way to judge as to the permissible fatigue stresses. He likewise does not attach much importance in this connection to a test consisting in subjecting samples of materials to a com-

FIG. 3 ENDURANCE DIAGRAM FOR VARIOUS METALS TESTED UNDER REPEATED STRESS

paratively small number of violent bends or twists and measuring the amount of the bending or twisting; though he does believe that such a test might be of value in testing material for crankshafts, in spite of the fact that it does not constitute a reliable index of the ability of a material to withstand long-time fatigue under working stress. In the author's opinion the best criterion for fatigue resistance is found in the *endurance diagram*, in which fiber stresses are plotted as ordinates and numbers of repetitions to produce failure are plotted as abscissae. Fig. 3 shows several such diagrams. This kind of diagram can be advantageously plotted on logarithmic cross-section paper, in which case the plotted points usually fall fairly closely along straight lines, at least up to one million repetitions of stress. The ordinates of such a stress endurance diagram show the fatigue strength for any given number of repetitions and the slope of the diagram gives an index of the relative fatigue-resisting strength for high stresses and for low stresses. Some uncertainty exists for the regions above four and five millions of repetitions, but this is true for all repeated-stress tests.

A fatigue failure of a machine part may start at some surface

irregularity, especially at a sharp inward-pointing corner, a groove or even a deep scratch. Polishing the surface of test specimens has been found to greatly increase their resistance to fatigue, especially under low stress and long-time tests. Another method of increasing resistance to fatigue stresses is by using generous fillets at shoulders. (*Journal of the Western Society of Engineers*, vol. 24, no. 6, June 1919, pp. 331-336 (for the paper), and pp. 336-340 (discussion), 4 figs. in the paper, *ep*)

### Molybdenum in Chrome and Chrome-Nickel Steels

**MOLYBDENUM IN COMMERCIAL ALLOY STEEL.** Data of an investigation of these steels published by a commercial organization. Only the most important conclusions are reported here.

The addition of molybdenum to chrome steel increases the elastic limit to a more marked degree than would the further addition of chromium. But the brittleness is not only not increased, but actually decreased with the addition of molybdenum, the greater toughness being shown by the higher elongation and reduction of area.

In chrome-nickel steel molybdenum is claimed to increase the toughness of the material to a considerable extent.

Data are given on the properties of a chrome-vanadium steel, with additions of molybdenum up to the one percent.

TABLE 1

Carbon	Manganese	Chromium	Silicon	Molybdenum
0.25-0.32	0.71-0.76	0.45-1.04	0.11-0.22 (On finished crankshaft)	0.32-0.46
Elastic Limit	Tensile Strength	Elongation Per Cent	Red. of Area Per Cent	Brinell Hardness

FIG. 4 THE RELATIVE PROPERTIES OF NICKEL-CHROME-MOLYBDENUM STEEL (LEFT) AND A NICKEL-MOLYBDENUM STEEL AT VARIOUS TEMPERATURES AND HEAT-TREATMENT CONDITIONS

As regards molybdenum in nickel steel, it is claimed that its addition increases the elastic limit, toughness and ductility, the effect being particularly pronounced when the steel is drawn at higher temperatures.

Molybdenum steels as a class permit a wide temperature range in which they can be heat-treated without detriment to their physical properties.

In the original article, figures selected from tests on commercial tonnages are given to illustrate this point, and it is claimed that, despite the extremely wide range in quenching temperatures, the variation in physical properties is slight. Tests made within a quenching range of as much as 300 deg. Fahr. have shown the practical uniformity of results. In all steels so tested the content of molybdenum varied from 0.25 to 0.40 per cent.

It is also stated that molybdenum steels are less liable to warp in the course of manufacture.

Of the three grades of chrome-molybdenum steels, the one of medium-carbon content is probably the most important commercially, as it is used for parts in automotive equipment such as crankshafts, connecting rods, front axles, etc. Tests on approximately 4000 finished crankshafts forged from this type of steel showed the average properties of the metal to be as given in Table 1.

Chrome-nickel-molybdenum steel was used on Liberty-motor crankshafts, and Table 3 gives the results of tests made by a commercial company.

TABLE 3

C.	Mn.	Si.	Cr.	Ni.	Mo.
0.305	0.69	0.52	0.98	3.05	0.54
0.236	0.30	0.08	0.74	2.85	0.32
Elastic Limit	Ultimate Strength	Elongation Per Cent	Red. of Area Per Cent	Izod	Brinell
130,000	142,000	20.5	65.0	67	303

The crankshafts were treated as follows: Forged and then twisted through the required angle; shaft is then annealed at 1600-1650 deg. Fahr. to relieve strains. Time at heat is about 1½ hr. Cooled in air. Heated in an electric furnace to 1475 deg. Fahr., held ½ hr. and quenched in water. Drawn at 1150 for 2 hr. Cooled in air and straightened before the temperature has reached 800 deg. Fahr.

Fig. 4 is of interest, as it gives the relative properties of a nickel-chrome-molybdenum steel (left) and a nickel-molybdenum steel (right) at various temperatures and heat-treatment conditions.

Molybdenum may be introduced into steel either as a ferroalloy or in the form of calcium molybdate. One of the large deposits of molybdenum in the form of molybdenum sulphide is located in this country at Climax, Colo., and is owned by the Climax Molybdenum Company. ("Molybdenum Commercial Steels," published by the Climax Molybdenum Co., abstracted through *Iron Age*, vol. 105, no. 6, Feb. 5, 1920, pp. 407-409, 3 figs., ep)

DEVELOPMENTS IN SOME OF THE RARER FERROALLOYS. The following extracts regarding some of the recent developments in the more uncommon ferroalloys are taken from British sources:

**Ferromolybdenum.** During the last couple of years the Canadian Imperial Munitions Board have produced 100,000 lb. of 70 per cent ferromolybdenum by the direct smelting of molybdenite concentrate at the works of the Tivani Electric Steel Co., Belleville, Ont. Vertical cylindrical furnaces of the single-phase type are employed, requiring 3000 to 4500 amperes at 50 volts per furnace. Each consists of an iron shell, lined with red brick, firebrick, silica brick, and carbon in succession, and resting on a concrete foundation. The lower electrode consists of a water-cooled bronze or copper block, from which iron rods project upward into the furnace bottom, and the upper electrode of a graphite or carbon rod. For the production of 70 per cent alloy from concentrate containing MeS, 75 and Fe 9 per cent, the charge consists of concentrate 100, lime 120, coke 10, and scrap steel 5 lb. Each furnace is tapped every 4 hr., the output being 1050 lb. of alloy per 24 hr. During the two years in which the plant was operated for the production of ferromolybdenum containing Mo 70, S 0.4, and C 4 per cent, the average composition of the product was Mo 70.43, S 0.38, and C 3.56 per cent.

**Ferrouranium.** Up to the present time the use of uranium in steel manufacture is not very fully developed or understood. The abundance of sodium uranate ( $\text{Na}_2\text{U}_2\text{O}_7$ ), a by-product from the extraction of radium and vanadium from carnotite, provides the material from which the oxides are produced. The alloy is made by reducing the oxides with carbon according to the following equations, and then mixing with iron:

The alloy usually contains from 25 to 35 per cent of uranium and under the microscope the uranium seems to be present, as the double carbide of iron and uranium,  $\text{Fe}_2\text{C}_2\text{U}_2$ , as a eutectic mixture of iron and carbon. It has been claimed that 0.5 per cent of uranium will replace several per cent of tungsten in tool steel, and the alloy is being used in making ternary uranium and quaternary uranium-tungsten steels.

**Ferrozirconium and Ferroboreon.** Ferrozirconium is one of the latest of the ferroalloys to come into use. It is made by the reduction of zirconia, with aluminum, by the thermite process, to the element and then alloyed with iron. In Great Britain a 20 per cent ferrozirconium has been used to some extent in the place of ferrotitanium.

**Ferroboreon** can be made by the reduction of a mixture of boron oxide and iron oxide with carbon in the electric furnace. Not much is known about this alloy, but experiments in France have shown that a very strong and tough steel can be made by using from 0.5 per cent to 2 per cent of boron.

**Ferroaluminum.** Ferroaluminum has been largely replaced in recent years by the metal aluminum, but it is suggested that a revival of its use would be desirable. It can be made by mixing scrap iron or iron ore with bauxite and reducing material. It formerly contained from 10 per cent to 20 per cent aluminum, but recent success in the production of ferroalloys indicates that a 50 per cent alloy could be produced. Aluminum is seven times as powerful as silicon and 28 times as strong as manganese in action upon the oxygen dissolved in steel, so that from one ounce to one pound of aluminum is sufficient to deoxidize a ton of steel. (*The Iron Age*, vol. 105, no. 7, February 12, 1920, p. 484, g)

## FOUNDRY

DIE-CASTING PARTS AND METALS. Brief statistical data of the

American die-casting industry, the description of die-casting machines, metals used and methods.

The article brings out such recent developments in the die-casting industry as casting of parts in metals fusible at high temperatures, such as various bronzes and brasses, in particular, aluminum bronze.

It would appear that for low-fusible alloys, soft low-carbon steel makes a very good material for dies, both in respect to its ability to stand up to the work and to the comparatively low cost of production of dies. For use with alloys having high melting points, however, low-carbon steel is entirely unsuitable and materials of the order of tool steels have to be used, as they retain their hardness at temperatures of the metal when injected into the die. However, they make the production of dies both more difficult and more costly.

In addition to this threads cannot be cast on parts made from such materials as aluminum bronze, as can be done with white metal. This inability to cast threads is attributed to the failure of the small pieces of metal used for thread cores to withstand the high temperatures present for any length of time. (Serial article, *Raw Material*, vol. 2, no. 1, Jan. 1920, pp. 468-474, 13 figs., d)

## FUELS (See Internal-Combustion Engines, Motor-Car Engineering)

### GAS PRODUCERS (See Motor-Car Engineering)

### INTERNAL-COMBUSTION ENGINES (See also Motor-Car Engineering)

#### Bureau of Standards Tests of Various Gasolines and Benzol Mixtures

**FUELS FOR AIRCRAFT ENGINES.** Symposium of three papers discussing the power characteristics of various fuels on the basis of tests made in the altitude laboratory of the Bureau of Standards and associated organizations.

The first paper (by H. C. Dickinson, W. S. James, E. W. Roberts, V. R. Gage and D. R. Harper, 3rd) presents data of tests of nine types of gasolines compared in turn with standard gasoline as a reference fuel.

Two of the fuels were representative American straight-run gasolines closely complying with the specifications for export gasoline. A third followed closely the specifications for fighting gasoline, while two others were slight variations of the fighting gasoline. These were imported from France. Two gasolines represented the average motor-car gasolines as sold by automobile filling stations, one of these being of eastern origin and the other a California gasoline. These fuels were tested quite thoroughly and among the properties the following were determined: Distillation curves, mean volatility, heat of combustion, critical solution temperature, chemical composition and magneto-optic rotatory power.

The reason of this latter test was as follows: In determining the properties of various organic mixtures it has been found that the presence of considerable proportions of compounds of the benzene group has a tendency to increase the rotation of the plane of polarization when a beam of monochromatic light is passed through the substance in a strong magnetic field. The presence of the benzene group has been thought by some to be associated with increased engine power. Thus, it was a conceivable hypothesis that the magnetic rotation might prove a convenient indicator of the power-producing ability of the fuel. This was worth while finding out, especially as this property of the gasolines could be measured very rapidly. Actually, no definite connection between the magneto-optic rotatory power and the engine performance of a gasoline was proved.

The tests on the whole have indicated that when the necessary carburetion changes have been made to suit each fuel, the difference in power-producing qualities of the various gasolines was

quite slight and the extreme difference was of the order of the magnitude of 5 per cent, which, considering the permissible variation in this kind of work, is very little.

The paper by E. W. Roberts discusses the power characteristics of Sumatra and Borneo gasolines. It appears that the sample of Sumatra gasoline tested develops slightly more horsepower than American standard export aviation gasoline, while the sample of Borneo gasoline develops slightly less horsepower. Fractional distillation shows a lower volatility for the sample of Borneo gasoline than for the sample of Sumatra.

The fuel economy with Sumatra gasoline was higher than with American export aviation gasoline except at the highest altitudes. The fuel economy of the Borneo gasoline may be said to have averaged about the same as that of American export aviation gasoline.

As regards the method of working up data, one feature of the lines of horsepower plotted against barometric pressure was particularly helpful. It was found that the intercepts of these lines on the axis of zero pressure were quite evenly spaced. For example, in the equation of the line

$$y = ax - b$$

wherein  $y$  = horsepower, and  $x$  = barometric pressure in cm. of

FIG. 5 DATA OF TESTS ON SUMATRA AND BORNEO GASOLINES AT THE BUREAU OF STANDARDS

mercury, the values of  $b$  increased by even increments for even increments of speed. The value of  $b$  is a function of the friction horsepower at that particular speed. Since the friction horsepower is entirely independent of the fuel employed, the values of  $b$  should be the same for each speed regardless of the fuel. Roughly estimating the equations of the various lines from the highest and the lowest horsepower in each case showed that the values of  $b$  were approximately the same for all fuels. Plotting these values of  $b$  against speed and drawing an average line through these points gave the final values which were employed for the lines of Fig. 5.

The power characteristics of 20 per cent benzol mixture were also investigated by E. W. Roberts, the fuel consisting of benzol and gasoline. From the results of these tests the following conclusions have been drawn: This mixture shows very little gain in power as compared with aviation gasoline (export) at the

lower altitudes and the lower speeds. There is very little gain in horsepower below 10,000 ft. Above this altitude, and at high engine speeds, the engine shows considerable gain in power, which at 29,300 ft. and 2100 r.p.m. is 5.8 per cent.

While the methods of measuring fuel consumption were not entirely satisfactory, the fuel consumption of the 20 per cent benzol mixture appears to be about 4 per cent greater than X, at speeds and powers where it gives its best performance. (National Advisory Committee for Aeronautics Report no. 47, preprint from 4th annual report, 35 pp., numerous curves, eA)

### Neptune Diesel Engine; Novel Scavenging Valve Arrangement

BRITISH DIESEL ENGINE. Description of the Neptune Diesel engine built by Swan Hunter and Wigham Richardson, known as the constructors of the *Mauretania*.

The new engine is based essentially upon the Polar motor of the Atlas Diesel Engine Company of Stockholm, but embodies several new features. It operates on the two-stroke-cycle single-acting principle, but there is one scavenging pump for each working cylinder arranged directly below it; air at atmospheric pressure is drawn into it on the up stroke and compressed to about 3 lb. per sq. in. on the down stroke. The control of the air admission and its discharge into a scavenging trunk *C*, Fig. 6, is effected by means of the valve *A*, which is actuated from the camshaft by means of an eccentric and vertical link. From the scavenging trunks *C* and *D*, which act as reservoirs, the scavenging air enters the working cylinders through ports at the bottom when these are uncovered by the piston on its downward stroke, the top

FIG. 6 CROSS-SECTION OF 1500-H.P. NEPTUNE MARINE OIL ENGINE

of the piston being shaped in a special manner to help in the effective admission of the scavenging air and discharge of the exhaust gases.

The piston valve *A* in combination with a change valve (not shown, but located back of *A*) serves another purpose. The scavenging cylinders are here used for starting purposes, compressed air at the low pressure of 100 to 150 lb. per sq. in. being admitted below the scavenging piston through the change valve and the piston valve *A*.

This indicates the object of the change valves. On starting up, these valves are placed in such a position that the admission pipe to the atmosphere is closed, but open to the compressed-air

supply, so that compressed air passes through the piston valve A into the scavenging cylinders.

The change valves are of the rotary type and are operated by means of a lever from the control station so that on starting up compressed air is admitted until the engine fires, after which the valves are immediately changed over to allow air to be drawn into the scavenging cylinders from the atmosphere. Only one valve, the fuel-admission valve, is required in each cylinder cover, as scavenging takes place through ports.

The scavenging cylinders, by the way, are supported on cast-iron columns at the front and by vertical steel columns at the back, with diagonal columns to provide stiffness. A pair of columns carries a pair of cylinders which permits ready standardization in 4-, 6- and 8-cylinder models.

A 6-cylinder engine, 18-in. diameter and 36-in. stroke, running at 115 r.p.m., develops 1500 i.h.p. (*International Marine Engineering*, vol. 25, no. 1, Jan. 1920, pp. 29-32, 2 figs., d)

## MACHINE SHOP (See Abrasives)

## MACHINE TOOLS

GEOMETRIC PROGRESSION OF SPEEDS IN MACHINE TOOLS, C. C. Stutz, Mem.Am.Soc.M.E. Presentation of a method of proportioning the speeds of machine tools which may be applied to almost any problem of this type.

In designing machine tools of any type it is now an accepted practice to so proportion the speeds that they will form among themselves a geometric progression, so that each speed is increased from the preceding speed by the same multiplier.

By multiplying the slowest speed  $a$  by the factor  $f$ , we obtain the second speed and so on through the whole series.

As a rule the number of speeds  $n$  is such that it cannot be obtained by a cone pulley alone, and the machine is therefore either back-gearled or triple-gearled, or perhaps even quadruple-gearled. In such a case it is a simple matter to obtain these gear ratios, as will be shown.

Assuming as an example a lathe with a four-step cone, ( $d = 4$ ), triple-gearled. This would give us four speeds with cone, four speeds with cone and back gears, four speeds with cone and triple gears; or 12 speeds in all, and the series (from the fastest to the slowest speed) would be:  $af^0, af^1, af^2, af^3, af^4, af^5, af^6, af^7, af^8, af^9, af^{10}, af^{11}$ .

It will be noticed that these three sections of the full series (each forming a series) bear the following relation to each other:

1 The second series can be obtained by dividing each member of the first series by  $f^1$ . In this case  $f$  to the fourth power is the ratio of the back gears.

2 The third series can be obtained by dividing each member of the first series by  $f^4 \times f^4 = f^8$ . In this case  $f$  to the eighth power is the ratio of the triple gears.

As the actual calculations are best carried out by logarithms we can summarize the above by writing

the log of ratio of back gears  $= d \log f$ .....[2]

the log of ratio of triple gears  $= 2d \log f$ .....[3]

and the log of ratio of quadruple gears  $= 3d \log f$ .....[4]

Numerical examples of the application of these formulæ are given and also formulæ for the case of a machine with two crankshaft speeds and for dividing the speeds between the two crankshaft ratios. (*American Machinist*, vol. 52, no. 3, Jan. 15, 1920, pp. 117-118, mp)

FIG. 7 RILEY MULTIPLE-RETORT STOKERS AND MECHANICAL COAL HANDLING AS INSTALLED BY ERITH, OF LONDON. INSTALLED ON NEW SHIPS ONLY

The writer assumes that the proper minimum speed  $a$  and maximum speed  $b$  for the given tool are given and that the total number of speeds desired  $n$  is also known. From this he derives the various speeds in the following manner.

Let  $n$  = total steps or intervals between total number of speeds  
 $f$  = ratio of one step or factor wherewith to multiply any speed to obtain the next higher speed, and

$d$  = number of steps in cone pulley.

Algebraically expressed, the various speeds therefore form the following series:

$$a, af, af^2, af^3, af^4, \dots, af^{n-1}, af^n$$

The last or fastest speed is expressed by both

$$af^{n-1} = b, \text{ or } f^{n-1} = \frac{b}{a}$$

$$f = \sqrt[n-1]{\frac{b}{a}} \dots \dots \dots [1]$$

## MARINE ENGINEERING

### Mechanical Stoking Aboard Ship, Its Technical and Economic Aspects

MECHANICAL STOKERS ABOARD SHIP, Charles H. Bromley. Progress of the application of mechanical stoking aboard ship. It is claimed that the introduction of oil fuel holds back their wider adoption at present. The adoption of mechanical-stoker feed aboard ship is clearly related to the introduction thereon of the water-tube boiler, and this latter is opposed in some quarters because of its alleged inferiority to the Scotch boiler in respect to reliability.

The author points out, however, that the experience of American war vessels and the vessels of the Emergency Fleet Corporation has shown that when properly handled the water-tube boiler is highly reliable and instances are given to prove this contention.

The gas from the producer enters the top header at the left-hand end and passes down the internal tube of the feed heater, which at the lower end is coned, and this tends to increase the velocity of the gas. The gas then expands into a settling chamber or pot, and in doing so drops a very large percentage of dust in suspension. It then leaves the settling chamber by an annular passage and passes up and down two or more banks of cooling tubes. In these tubes and the headers more dust is deposited. Finally, the gas passes up two or more large-diameter tubes, which are fitted with fine-gauze filters of conical shape and filter fitting the bore of the tube at the lower end; to this a cross-handle is attached, which allows the filter to be easily withdrawn through the door in the top header. An arrangement is also provided whereby any filter can be closed off and withdrawn for cleaning

feed heater and filter is very small and can be easily accommodated on the dashboard on the side opposite to the producer. Many other forms of filters will, no doubt, be possible, but the author thinks it will be difficult to evolve a design which at once meets the requirements and is of less weight and size.

The material found in the filter is merely the fuel dust, which is quite dry and clean, and no trace of any tarry substance likely to cause trouble with the engine has ever been found.

The mixing valves and refractory lining of the producer are described in some detail. As regards the weight of the producer, it is stated that the plant which has a grate 12 in. in diameter, equivalent to 50 hp., weighs with its connections approximately 2.75 cwt. (308 lb.), corresponding to a weight of 6 lb. per hp., notwithstanding the fact that cast iron was used throughout. This

1. Fuel inlet pipe
2. Adjustable fuel feed and ash-discharge vent.
3. Fuel feed valve
- 3a. Friction drive for feed valve.
- 3b. Handle for independent hand operation of feed valve.

(Note that the position of the handle indicates the location of the feed aperture.)

4. Ash discharge valve
- 4a. Friction drive for ash discharge valve
- 4b. Handle for ash discharge valve (Similar to that on fuel feed valve.)
5. Water pump.
6. Main operating gear shaft driven direct from engine.

7. Totally enclosed and continuously lubricated driving gear for the fire-bar camshafts. These also drive the water pump, fuel feed valve and ash discharge valve.

8. Pipe conveying steam and air to the underside of the fire.

9. Air supply pipe from interior of jacket to vaporizer.

10. Fire bars, alternate sections pivoted at alternate ends, the free ends being vibrated section by section and successively by cams on revolving shafts.

11. One of the cams for vibrating the fire-bars.

12. Diagrammatic arrangement of producer and scrubber.

FIGS. 9 AND 10 GENERAL ARRANGEMENT OF THE SMITH PORTABLE GAS-PRODUCER PLANT

without stopping the action of the producer, but this is not likely to be required for vehicle work. The gas on leaving the filters is clean enough for all practical purposes and carries no more dust than is drawn into the air inlet of a carburetor when the roads are dusty. The cleaning of the filter is simple and only takes two or three minutes. The doors are opened, the gauze filters withdrawn and water is poured in at the top doors and all dust washed out; the gauze filters are then shaken and replaced. The water from the feed pump on the producer enters the feed heater at the bottom opening and leaves at the top of the vaporizer. This cools the gas considerably, and also recovers much valuable heat which would otherwise be lost. The combined

does not include, of course, the weight of the engine itself, but only that of the producer and its appurtenances.

As regards the engine design, the author states that the conventional gasoline engine is entirely unsuitable for use with producer gas. With such a cheap fuel a large, comparatively slow-running engine could be used with approximately the same characteristics as a stationary engine. A higher compression with a half-compression device is essential, as a pressure of 120 to 150 lb. gage would be necessary to obtain a fair economy with producer gas. The author recommends, for example, an engine such as the four-cylinder stationary type, 6½ in. diameter by 7½ in. stroke, running at 600 r.p.m.

As regards fuels, the author tested anthracite, semi-anthracite, coke, charcoal, peat, corneobs and straw, all of these fuels proving satisfactory under certain conditions.

In an editorial article on page 85 of *Engineering* for January 16, 1920, attention is called to the fact that in the paper no information is given as to the degree of reliability to be expected from the system described by Mr. Smith, a point which would be of interest to prospective users, especially if they had had expe-

FIG. 11 SCRUBBER FOR THE SMITH GAS-PRODUCER PLANT

rience with stationary producer plants. (Paper read before the Institution of Automobile Engineers, Jan. 8, 1920, abstracted through *The Automobile Engineer*, vol. 10, no. 134, January 1920, pp. 22-32, 9 figs., and *Engineering*, vol. 109, nos. 2819 and 2820, Jan. 9 and 16, 1920, pp. 59-64 and 92-95, 9 figs., dA)

### Single-Sleeve Duplicated-Piston V-Type Motor

**DUPLEX CAR AND ENGINE.** Description of a light British car with an unusual type of engine.

The Duplex motor, Fig 12, is of the single-sleeve duplicated-piston type with the pistons running in conjointly twinned cylinders, and consists of a detachable headed monoblock of 8 cylinders of only 56 mm. (2.20 in.) bore by 75 mm. (2.95 in.) stroke.

The ports, inlet and exhaust are cut half around the outer side of each cylinder and are opened and closed by crankshafts through tiny connecting rods attaching to lugs at the bases of the sleeves (Fig. 14). These sleeves, which are of cast iron, carry three rings each, the top one wider than the other two, and as the ports are 5 16 in. deep on the exhaust side and 1/4 in. deep on the inlet, the construction gives a large valve area with a comparatively slight sleeve motion (1 1/8 in.).

The pistons carry their three rings in the middle of their trunks and the gudgeons are rather lower than usual, because of the connection in each pair to a common crankpin on the short four-throw crankshaft.

The crankshaft is mounted at the ends only in two roller bearings, the rollers being hollow to enable them to be link-caged and distanced somewhat like the rollers in a chain. The sleeve shafts,

on the other hand, are mounted in long plain bearings with bolt thrusts at the end and drive is by helical gearing from the front end of the crankshaft. The sleeve shaft also carries an eccentric actuating a horizontal piston pump internally spring-loaded, which draws oil from a large deep rearward sump by way of a non-return ball valve (right-hand side of Fig. 13) and delivers it downward again to a gallery lead in the casting for distribution to four transverse troughs from which dippers on the big ends effect splash lubrication to all interior surfaces.

It is claimed that this design permits obtaining rather interesting physical results; namely, a cylinder capacity of ap-

FIG. 12 DUPLEX SLEEVE-VALVE MOTOR, PLAN VIEW WITH HEAD BLOCK DETACHED, SHOWING THE SEMI-CIRCUMFERENTIAL PORT AREAS

FIG. 13 DUPLEX SLEEVE-VALVE MOTOR, SECTIONAL END VIEW FROM THE FRONT

proximately 80 mm. (3.15 in.) by 75 mm. (2.95 in.) halved in area so as to produce a simultaneous effort under the medium long stroke or "internal combustion" conditions of 56 mm. (2.20 in.) by 75 mm. (2.95 in.). It is claimed that in this manner all the capacity of the short-stroke type is obtained for sustained high speed without its extravagance and jerky inflexibility at low and medium speeds. In fact, it is claimed that a motor is obtained in which the power curve is practically a straight line from the rated 10 hp. at 1000 r.p.m. up to 33 hp. at 3000 r.p.m.

As regards the valve mechanism, it is stated that the valve shafts having only frictional resistance to overcome are doing next to no work and their rotation absorbs little power, while the system affords easy timing. It is claimed the motor presents unusually good cooling facilities. (*The Auto Motor Journal*, vol. 25, no. 3/993, Jan. 15, 1920, pp. 66-68, 7 figs., dA)

## POWER-PLANT ENGINEERING

### Suggested Form of Reporting Steam Power-Plant Performance to Give Comparable Data

ESSENTIAL STATISTICS FOR GENERAL COMPARISON OF STEAM-POWER-PLANT PERFORMANCE, W. S. Gorsuch. Method for preparing statistical reports relating to power generation in steam power plants based on coal and load characteristics of the plant; suggested tabular forms for reports.

The principal difficulty with operating statistics of steam power plants as published by various state and government bodies is that they are inadequate for the purpose of determining the efficiency of a plant or making general comparisons between different plants. Bare figures of coal consumption per kw-hr. are given without information as to the quality of the coal and data as to the character of the load on the station. When load factors are given the figures are misleading, because they are computed upon different bases; thus, gross output is used in some cases and net output in others.

The author recommends that the following items be recorded in statistical reports relating to power generation in steam power plants and that they be expressed in a uniform manner. These items are said to reflect the influence of station design and arrangement of apparatus, methods of operation and management, load, quality and kind of fuel used and also indicate the character of the load imposed upon the station.

#### I Coal Characteristics of the Plant:

- 1 Average B.t.u. supplied to plant per kw-hr. net output
- 2 Thermal efficiency of plant in per cent
- 3 Average B.t.u. per dollar, coal as received (moist basis)
- 4 Coal factor or pounds of coal per kw-hr. net output (moist basis)
- 5 Average B.t.u. per pound of coal as received (moist basis)
- 6 Cost of coal per ton (2240 pounds) delivered alongside of the plant
- 7 Kind and character of coal
- 8 Cost of coal in cents per kw-hr. net output.

#### II Load Characteristics of the Plant:

- 9 Average daily load factor of load
- 10 Maximum load for the year
- 11 Yearly load factor of load
- 12 Kilowatt-hours net output for the year (kilowatt-hours sent out from the a.c. bus)
- 13 Installed rated capacity, that is, the aggregate maximum continuous rating of the generators in kilowatts
- 14 Average kilowatt-hours net output per kilowatt installed rated capacity.

Items 1, 2, 3, 8, 11 and 14 can readily be computed from items 4, 5, 6, 10, 12 and 13.

As regards the coal characteristics, generally speaking, the highest thermal efficiency is obtained when burning the highest quality of coal. On the other hand, a low grade of coal purchased at a low price may result in a better commercial efficiency. Therefore, as an index of the commercial efficiency of the plant, one has to have both the B.t.u. per kw-hr. net output and the B.t.u. per dollar.

The character of the load carried has a marked influence on plant efficiency since a fluctuating load and a load with sharp peaks and low load factor require more coal than an equally steady load or a load with a high load factor. The load conditions must therefore be known in order to compare the performance of the two plants, and these are best indicated by the ratio of the average load to the maximum load for the same

period; this is known as the load factor and is usually expressed in percentages.

There is, however, in the electrical industry no uniform method for determining the load factor. The writer recommends the use of the daily load factor which is the ratio of average net output during 24 hr. to the net maximum load multiplied by 100 in order to express the load factor in percentages. In comparing power-station statistics, which are usually on a yearly basis, the average daily load factor should be used because it is more representative of the operating conditions in the plant itself than the load factor based on the maximum of the month or year. The plant factor, which is the ratio of the average hourly load for the year to the rated capacity of the plant, is a measure of the utilization of the installed capacity. This is obtained by dividing 8760 into item 14.

For the purpose of illustrating the method and advantages for preparing statistical reports as described here, the following comparison is made between a few of the items of two plants, A and B, which have similar load characteristics but which use coal differing in quality and price:

I Coal Characteristics of the Plant:		Plant A	Plant B
1	Average B.t.u. supplied to plant per kw-hr. net output.....	22,400	25,600
2	Thermal efficiency of plant in per cent.....	15.24	13.34
3	Average B.t.u. per dollar, coal as received (moist basis).....	5,226,666	5,734,400
4	Coal factor, or lb. of coal per kw-hr. net output (moist basis).....	1.60	2.00
5	Average B.t.u. per lb. coal, as received (moist basis).....	14,000	12,800
6	Cost of coal per ton (2240 lb.) delivered alongside plant.....	6.00	5.00
7	Kind of coal.....	Bituminous	Bituminous
8	Cost of coal in cents per kw-hr. net output.....	0.428	0.446
II Load Characteristics of the Plant:			
9	Average daily load factor of load.....	Interval of maximum load, 1 hr. 50	54
10	Maximum load for the year.....	90,000	80,000
11	Yearly load factor of load.....	40	38
12	Kw-hr. net output for the year (kw-hr. sent out from the a.c. bus).....	315,460,000	217,248,000
13	Installed rated capacity, i.e., aggregate max. continuous rating of the generators in kw.....	125,000	100,000
14	Average kw-hr. net output per kw. installed rated capacity.....	2,525	2,173

### PRODUCER GAS (See Motor-Car Engineering)

### TESTING OF MATERIALS (See Engineering Materials)

### TESTING AND MEASUREMENTS

#### Theory of Rocket Action; Goddard's Calculation of Rocket Capable of Passing Beyond the Range of Attraction of the Earth

A METHOD OF REACHING EXTREME ALTITUDES, Robert H. Goddard. Discussion of rocket action, the theory and design of rockets, and also the use of rockets for carrying recording instruments to the upper reaches of the atmosphere and beyond.

The problem considered in the paper was to determine the minimum initial mass of an ideal rocket necessary in order that on continuous loss of mass a final mass of 1 lb. would remain at any desired altitude.

An approximate mathematical method has shown that surprisingly small initial mass would be needed to carry a rocket to extremely high altitudes provided the gases were ejected from the rocket at a high velocity and also provided that most of the rocket consisted of propellant material.

The reason for this is, namely, that the velocity enters in the expression for the initial mass as an exponent, so that if the velocity of the ejected gases be increased fivefold, the initial mass necessary to reach the given height will be reduced to the fifth root of that required for the lesser velocity.

The solution of the problem of constructing a rocket of reasonable dimensions to reach extremely high altitudes necessitated the determination of the extent to which efficiency could be carried in a rocket of new design. The term efficiency as applied to rockets means the ratio of kinetic energy of the exploded gases to the heat energy of the powder, the kinetic energy itself being calculated from the average velocity of ejection—obtained indirectly by observations on the recoil of the rotors.

Tests have shown that the powder used in an ordinary rocket constitutes only a very small fraction of the total mass and the efficiency of the rocket is as low as 2 per cent. Experiments were performed with the object of increasing the average velocity of ejection of the gases. Charges of dense smokeless powder were fired in steel chambers provided with smooth tapered nozzles, the object of which was to obtain the work of expansion of the gases, much as is done in the DeLaval steam turbine. The efficiencies and velocities obtained in this way were very high, the highest efficiency being over 64 per cent and the highest average velocity of ejection being slightly under 8000 ft. per sec. Moreover, these velocities were proved to be real velocities and not merely effects due to reaction against the air resulting from firing the same steel chambers in vacuum and observing the recoil.

Since, however, a heavy steel chamber could not be used in a rocket, a reloading mechanism was designed in which successive charges were fired in the same chamber of light weight and small mass, so that most of the mass of the rocket could consist of propellant.

Regarding the heights that could be reached by the above method, it would appear that a mass of 1 lb. could be elevated to altitudes of 35, 72 and 232 miles by employing initial masses of from 3.6 to 12.6, from 5.1 to 24.3 and 9.8 to 89.6 lb., respectively, which is only a very small fraction indeed of what the initial masses would have to be in order to raise to the same heights a rocket of the Costen ship type.

In the course of the investigation several interesting methods were developed for deducting and measuring gaseous rebound: one to measure the force of the rebound, and another, called "impulse motors," for measuring the magnitude per unit area produced by the rebound in gases.

Among other things is discussed the question of calculating the minimum mass required to raise 1 lb. to an infinite altitude. The meaning of this term is as follows: Theoretically a mass projected from the surface of the earth with a velocity of 6.95 miles per sec. would, neglecting air resistance, reach an infinite distance after an infinite time, which in ordinary language means that it would never return to the earth. Actually, such a mass would not reach an infinite distance, but would come under the gravitational influence of some other heavenly body and follow the course prescribed by the resultant between the two forces acting upon it.

The construction of a rocket that would pass the sphere of gravitational attraction of the earth does not appear to present insuperable difficulties, the main difficulty lying in the finding of means of proving that such extreme altitudes as would be considered in this case had been reached. The only reliable procedure would be to send the smallest mass of flash powder possible to the dark surface of the moon when in conjunction in such a way that it would be ignited on impact. The light would then be visible in a powerful telescope.

Mathematical computations have shown that with the telescope of 1 ft. aperture a mass of flash powder of about a dozen pounds exploded on the surface of the moon would be very clearly visible, but to carry such a mass of flash powder to the moon a rocket of an initial mass varying between 8 and 16 tons would be needed.

The author of the paper plainly states that this plan of projecting a mass of flash powder to the surface of the moon, although a matter of much general interest, is not of obvious scientific importance. He adds that there are, however, developments of the general method under discussion which involve a number of important features not herein mentioned which could lead to results of much scientific interest. These developments involve

many experimental difficulties but they depend upon nothing that is really impossible.

It appears, therefore, that contrary to the impression given by newspaper reports of the paper, the author does not consider that his rockets in their present stage can be employed for establishing a system of passenger transportation between our planet and its heavenly neighbors. (*Smithsonian Miscellaneous Collections*, vol. 71, no. 2, publication 2540, 1919, 69 pp. and 10 plates of figures, *et.c.*)

## VARIA

**NEW BRITISH PATENT ACT.** This act was finally approved on December 23, 1919, and is now in force, except a few sections. It makes numerous alterations and amendments to the act of 1917, the most important of which are as follows:

The period of provisional protection has been increased from six to nine months. The duration of the life of a patent has also been extended and is now sixteen years instead of fourteen, as hitherto.

Provisions have been made to simplify the procedure for obtaining the prolongation of the life of the patent when it has been affected by war conditions.

An important alteration of the previous laws has been made in the way of extending the ground of opposition to the grant of a patent so as to include prior publications other than patent specifications, which makes it possible to now use references to newspaper or technical periodicals. But the examiner is not allowed to cite publications other than British specifications in opposition to the grant of a patent.

Under the new laws an inventor does not prejudice his right to a patent if he reads a paper containing a description therein before a learned society and has before such reading given notice of his intention to do so.

Extensive modifications not suitable for abstracting have been made in the closes referring to the working on a commercial scale of new inventions required under the patent laws. The system of granting compulsory licenses has also been modified in several material respects. On the whole, however, the old provisions as to the method of payment, etc., which made the British system so different from the American have been maintained in their most essential records. (*Compare Engineering*, vol. 109, no. 2819, Jan. 9, 1920, pp. 53-54, *g*)

**WOMEN WORKERS IN BRITAIN.** Approximately 5000 firms in Great Britain have been asked by the Women's Industrial League for a statement of their experience of women as industrial workers. Over 1400 replies have been received, covering a wide field in engineering and other trades.

The replies show that 1422 firms were employing 79,700 women at the end of May, 1919, as compared with 43,200 before the war and 245,300 during the war. Of 382 firms who employed women before the war, 67 propose to increase the number, in consequence of the larger experience of women's work gained by them; while of 764 who employed women for the first time during the war, 228 propose to retain them. These firms do not comment on the present labor situation. A further 97 firms state that they would be willing to retain women but for trade union opposition. Taking all the figures, the estimate is that over 60 per cent of those who have tested women's work are ready to continue employing them. (*The Iron Trade Review*, vol. 66, no. 8, February 19, 1920, p. 558, *g*).

## CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

# ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

## Research Associations in Great Britain

THE proposed Research Associations in Great Britain which were described in the letter of Mr. Bancel in MECHANICAL ENGINEERING for August have been organized, and a recent circular issued from the Department of Scientific and Industrial Research of Great Britain gives the following list of Associations which have received licenses from the Board of Trade:

British Boot, Shoe and Allied Trades Research Association, Technical School, Abington Square, Northampton. Secretary, John Hinkman, M. A., M. Sec.  
British Cotton Industry Research Association, 108, Deansgate, Manchester. Secretary, Miss B. Thomas.  
British Empire Sugar Research Association, Evelyn House, 62, Oxford St., London, W. 1. Secretary, W. H. Giffard.  
British Iron Manufacturers Research Association, Atlantic Chambers, Brazenose Street, Manchester. Secretary, H. S. Knowles.  
British Motor and Allied Manufacturers Research Association, 39, St. James Street, London, S. W. 1. Secretary, Horace Wyatt.  
British Photographic Research Association, Sicilian House, Southampton Row, London, W. C. 1. Secretary, Arthur C. Brookes.  
British Portland Cement Research Association, 6, Lloyd's Avenue, London, E. C. 3. Secretary, S. G. S. Paulisset, A.C.G.I., F.C.S.  
British Research Association for the Woolen and Worsted Industries, Bond Place Chambers, Leeds. Secretary, Arnold Frohisher, B. Sc.  
British Scientific Instrument Research Association, 26, Russell Square, W. C. 1. Secretary, J. W. Williamson, B. Sc.  
British Rubber and Tyre Manufacturers Research Association, c/o Messrs. W. B. Peat & Co., 11, Ironmonger Lane, E. C. 2.  
The Linen Industry Research Association, 3, Bedford St., Belfast. Secretary, Miss M. K. E. Allen.  
Glass Research Association, 7, Seamore Place, W. 1. Secretary, E. Quine, B. Sc.  
British Cocoa, Chocolate Sugar Confectionary and Jam Trades Research Association, 9, Queens Street Place, E. C. 4. Secretary, R. M. Leonard.

The Department of Scientific and Industrial Research of Great Britain has approved certain research associations which have not yet been licensed by the Board of Trade. These associations are given in the list below:

British Music Industries Research Association  
British Refractory Materials Research Association  
British Non-Ferrous Metals Research Association  
Scottish Shale Oil Research Association.

The associations which are being considered by the Department of Scientific and Industrial Research are listed below:

British Launderers Research Association  
British Electrical and Allied Industries Research Association  
British Aircraft Research Association.

The silk manufacturers, the leather trade and the master bakers and confectioners are preparing articles of association for consideration by the Department.

Do the lists above suggest to our members the advisability of the formation of similar research associations in this country? The Heating and Ventilating Engineers, the National Cannery Association, the Association of Steel Manufacturers are all indicative of such work in America, but there is need for more cooperative work. The Research Committee feels that we will have accomplished much when those engaged in similar lines of manufacture can forget trade differences and cooperate in all active work for the development of knowledge in science and the arts.

## Kansas State Research Council

The State of Kansas has recently organized the Kansas State Research Council, which bears the same relation to the State of Kansas as the National Research Council does to the United

States. Professor G. C. Shaud of the University of Kansas and Dean A. A. Potter of the Kansas State Agricultural College are on the Executive Committee of the Council.

## Research of the American Society of Heating and Ventilating Engineers

The first reports of the researches from the Research Laboratory of the American Society of Heating and Ventilating Engineers at the laboratory in Pittsburgh under the direction of Director John R. Allen were made at the annual meeting of the society in January. A paper on the total heat transfer through radiators and the amount of radiant heat from a radiator, as well as the tests on coal stoves made by Professor Allen and Mr. Rowley, were given. The excellent work of this society as shown in these reports is highly commendable, and the Research Committee of The American Society of Mechanical Engineers greatly appreciates their activity.

## Instrument Specifications

The Firestone Tire and Rubber Company are preparing a code of specifications for Bourdon tube pressure gages, recording thermometers, indicating mercurial thermometers and test gages. These are being prepared under the direction of Mr. F. J. Schlink, Physicist in Charge of the Instruments Inspection Department, and Chairman of the Special Committee on the Permanency and Accuracy of Indication of Engineering Instruments of The American Society of Mechanical Engineers.

## A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulae or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

**Apparatus and Instruments A2-20** The investigation on altitude effect of air-speed indicators is nearing completion and show conclusively that the compressibility of air may be legitimately omitted in determining the law of action of the usual venturi tubes; that viscosity must not be neglected in low-speed flights; that at low speeds the indication of the venturi is not directly proportional to the air density nor to the square of the speed but departs noticeably from this relation. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Cement and Other Building Materials A1-20** Crushed-Slag Aggregate. Crushed slag as a coarse aggregate produces concrete of as high or higher strength than gravel. The experiments already made are not extensive enough to determine the durability of slag, but so far as they have been carried on there have been no signs of disintegration due to sulphide sulphur. Slag sand does not produce an easily workable concrete when used as fine aggregate because of its lack of fine material. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Explosives and Explosions A1-20** Propagation of Flame in Pipes and Effectiveness of Arresters. The Underwriter's Laboratory of Chicago has issued a report on the above subject prepared by A. H. Nuckolls for the E. I. du Pont de Nemours and Company. The investigation was made by filling a pipe with a vapor-air mixture containing a known percentage of vapor and igniting by electric spark. The pressures developed were measured by recording gas-engine indicators and the effectiveness of arresters was determined by examining the products remaining in the pipe. The speed of propagation was not investigated. The results show that the pressure is dependent on the nature of the vapor and the relative proportion of air and is influenced by the size

and length of the pipe. Gasoline and ether produced maximum pressures from 75 lb. per sq. in. in 1/2-in. pipes to about 150 lb. per sq. in. in 6-in. pipes. Alcohol and acetone gave 50 to 100 lb. per sq. in. while amyl acetate and light oil gave about 70 lb. Rich and lean mixtures gave lower pressures than the mixture having the right composition for complete combustion. Pressures were found to increase with the diameter of the pipe but not with the length of the pipe. The propagation appeared to be progressive combustion. Arresters of the screen type were found to be more satisfactory than glass, wool or metal chips. Forty mesh, No. 31, B. & S. brass wire gave the best result, especially when made in the cone shape, the length of the axis being twice the diameter of the base. Multiple coarse-mesh screens were ineffective. The effectiveness of arresters is influenced by the nature and proportion of the vapor, size and length of pipe and location of arrester. Flames from ether and gasoline are more difficult to arrest than those from other vapors. The larger the amount of air the more easily is propagation arrested. In large pipes the arresters are not as effective as in small pipes.

In connecting tanks the connecting pipe should not be over 4 in. in size; preferably it should be 1/2 in. or 1 in. The length should not be greater than 20 ft. Double cone screens should be employed. Flat screens may be used in 2-in. vent pipes.

This investigation should be continued over a wider range. Address Engineering Department, E. I. du Pont de Nemours Company, F. A. Wardenburg, Assistant Chief Engineer, Wilmington, Del.

**Heating A1-20 Coal Stoves.** The efficiency of the standard design of base-burner coal stoves has been found to be about 70 per cent under ordinary operation. The two stoves tested showed an excessive amount of air leakage so that the percentage of CO in the exhaust gases was about 4 per cent. After leaks were sealed the percentage rose to 10 per cent. The stove under ordinary conditions gave about 75 per cent efficiency, but at the higher rates of combustion it is impossible to get this efficiency due to the lack of radiating surface from which the heat can be given. The tests were made at the University of Minnesota by Professors John R. Allen and F. B. Rowley. Address John R. Allen, Bureau of Mines Building, Pittsburgh, Pa.

**Heating A2-20 Radiant Heat from Direct Radiators.** Director John R. Allen and Prof. Frank B. Rowley have presented a paper to the American Society of Heating and Ventilating Engineers on tests made at the University of Minnesota to determine the amount of heat radiated from a direct cast-iron steam radiator. The radiator was placed within a tank from which the air was exhausted and the amount of heat radiated was determined from steam condensation, measuring the heat input in an electrically heated boiler. The experiments indicate that the Stefan-Boltzmann law holds. The amount per sq. ft. of radiation is equal to

$$Q = 0.157 R \left[ \left( \frac{T_s}{100} \right)^4 - \left( \frac{T_r}{100} \right)^4 \right]$$

In this formula  $Q$  represents the heat in B.t.u. per sq. ft. per hour radiated from the radiator.  $R$  is the proportion of the total radiator surface which is effective in radiating heat. This varies from 0.55 in one-column radiators to 0.33 in four-column radiators, with a value of about 0.8 for wall radiators. The constant 0.157 was determined from physical experiments on clean cast iron, the value being less than this when aluminum paint is used. Table 1 gives the values of the constant  $D$  which is 0.15 in the formula above.

TABLE 1.					
Condition of surface:	Temp.	Temp.	B.t.u.	Value of	
	of tank				
	deg. Fahr.	deg. Fahr.	radiating	constant $D$ .	
Cast iron, rusty, . . . . .	70	215	180	0.142	
Cast iron, painted black, . . . . .	70	215	180	0.152	0.129
Cast iron, clean, . . . . .	70	215	186	0.148	
Aluminum paint, . . . . .	70	215	181	0.151	0.104
Physical experiment, clean cast iron, . . . . .	70	215	198	0.157	

For practical work the authors suggest 0.157 be used in problems. With steam temperature at 215 deg. Fahr. and room temperature at 70 deg. Fahr. the radiation amounts to 200 B.t.u. per sq. ft. of rated surface per hour. Address Director John R. Allen, Bureau of Mines Building, Pittsburgh, Pa.

**Heating A3-20 Heat Transfer from Direct Radiators.** Director John R. Allen of the Research Laboratory of the American Society of Heating and Ventilating Engineers has presented a paper to the Society at its annual meeting January, 1930. His investigations show that the heat transfer from radiators is made up of two parts; that transmitted by radiation and that transmitted by conduction. The final formula is given as

$$Q = 0.157 R \left[ \left( \frac{T_s}{100} \right)^4 - \left( \frac{T_r}{100} \right)^4 \right] + (t_s - t_r)$$

In this equation the first terms give the heat delivered by radiation and the last term the heat by convection; the constant for which is unity. In the equation  $Q$  represents the B.t.u. per sq. ft. of total radiator surface per hour.  $R$  represents the ratio of the radiating surface to the total surface.  $T_s$  is the absolute

temperature of the room in fahrenheit degrees and  $T_r$  the absolute temperature of the steam in fahrenheit degrees, while  $t_s$  and  $t_r$  are in degrees fahrenheit. The value of  $R$  for tension section radiators is about 0.55 for one-column radiators, 0.50 for two-column radiators, 0.38 for three-column radiators, 0.33 for four-column radiators and about 0.8 for wall radiators. These constants vary with the height of the radiator and with the

FIG. 1 HEAT TRANSMISSION FOR DIFFERENT HEIGHTS AND NUMBERS OF COLUMNS OF RADIATORS

FIG. 2 HEAT TRANSMISSION FOR DIFFERENT WIDTHS OF RADIATORS

FIG. 3 HEAT TRANSMISSION FOR RADIATORS OF VARYING LENGTH

number of sections in the radiator, increasing with the decrease of height and decrease of number of sections. Curves and tables show the effect of heights of radiator, widths of radiator, lengths of radiator, temperature of steam and room, humidity, air circulation, final painting and position of radiator. The results are

given in curves and tables in the original paper and the curves are reproduced below. The effects of grillwork or shields in front of the radiator are shown to reduce the heating capacity from 10 to 20 per cent, although when radiators are placed below seats reductions amount to 35 or 40 per cent. Address John R. Allen, Director, Bureau of Mines Building, Pittsburgh, Pa.

**Heating A4-20** Kiln Coils for Wood Drying. Return-bend heating coils gives a more uniform distribution of heat in kilns than coils built up of headers and should be used when possible. Forest Products Laboratory, Address Director, Madison, Wis.

**Machine Design A1-20** Six-Throw Automobile Crankshafts. A report has been issued by the Bureau of Standards to certain manufacturers on the elimination of certain difficulties in making G-throw automobile crankshafts. It was found that much of the trouble was of a mechanical rather than a metallurgical nature. Opportunities were found for improvements in the

metallurgical treatment of the process. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Metallurgy and Metallography A2-20** Microstructure of Steel Subject to Sudden Heating. Martensite structure has been observed in the superficial layers of metal in the bores of guns and pressure plugs. This has been probably due to rapid heating and high temperature followed by sudden cooling. This has been shown to be true by a sudden heating and cooling of the metal produced by the intermittent discharge of an electrode close to the metal surface. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Metallurgy and Metallography A3-20** Spiegeleisen. Production of Spiegeleisen in Blast Furnaces, by P. H. Royster. War Minerals Investigations Series No. 6, Bureau of Mines. Address Van H. Manning, Director.

**Properties of Engineering Materials A2-20** Fatigue Tests on Tubing. Tests in progress on iron and copper tubing under repeated stress indicate that pipes are seriously weakened by surface irregularities, especially by makers' names stamped on the pipe. Bureau of Standards, Washington, D. C. Address W. S. Stratton, Director.

**Properties of Engineering Materials A3-20** Electric Welding of Metal. A comparison of tensile tests on welded metal plates shows that the mechanical properties of the metal produced at the Bureau of Standards are uniformly lower than those of the Wirt-Jones test conducted by the Welding Research Subcommittee. The personal element appears to be an appreciable factor in welding. Microscopic examination and hardness tests do not show any well-defined relation between physical properties and microstructure because of premature failure due to flaws. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Rubber and Allied Substances A1-20** Gutta Percha. Weston A. Price, M.S., D.D.S., of Research Institute of the National Dental Association, in a report of laboratory investigations on tooth-filling materials discusses the expansion of gutta percha with temperature change and also the action of the evaporation of solvents on gutta percha. He gives a report of Dr. Dayton C. Miller of Case School of Applied Science. On heating and cooling a sheet of pink gutta percha the sheet contracted greatly in the direction which appeared to be that in which it was rolled, while expansion took place in the direction perpendicular to this. In heating from 22 deg. fahr. to 211 deg. fahr. the contraction of area was 14.7 per cent. A second piece 70 mm. by 70 mm. was heated from 70 deg. fahr. to 211 deg. fahr., changing in area to 63.0 mm. by 72.5 mm. The thickness increased from 0.843 mm. to 0.912 mm. This means a diminution of length of 10 per cent, an increase of breadth of 3 per cent and an increase of volume of about 1 per cent. The test under a rising and falling temperature showed a variation in the form of a hysteresis curve. On annealing in boiling water for 10 min. somewhat similar results were obtained.

Chloroform was found to absorb gutta percha. When the solvent was allowed to evaporate the volume of a thick solution just firm enough to hold its shape was 260 per cent of the volume when all of the solvent was driven off. Address Dr. Weston A. Price, Research Institute of National Dental Association, Cleveland, O.

**Wood Products A1-20** Laminated-Wood Forms. Solid artificial limbs are difficult to obtain without checking. Built-up limb blanks have been proposed, made with water-resistant caseln glue. Little or no waste is experienced in this way.

After 175 games, laminated maple bowling pins were returned for photographing. They were in excellent condition, but one gave way in a caseln glue joint. This is not considered a defective pin, as solid pins often split. Birch and caseln pins have stood up equally well. Birch pins are not so satisfactory. Two sets of maple pins are being made up to be combined with two sets of standard pins. Laminated gun stocks of black walnut are to be shipped to the Ordnance Department. Laminated shoe lasts are being tried by the Badger State Shoe Company. Forest Products Laboratory, Madison, Wis. Address Director.

**Wood Products A2-20** Drying Schedule for Air-Seasoned Oak. Table 3 which follows for 4-in. by 4-in. plain-sawn oak with 15 per cent moisture content gives the same result as would be reached by 9 to 12 months of air seasoning. After stock is dry, kiln is held at 145 deg. fahr. with 80 per cent humidity for 10 hours to balance moisture content and prevent warping.

**Wood Products A3-20** Wood Preservatives. The Forest Products Laboratory has treated sap-pine ties and red-oak ties with sodium fluoride, zinc chloride and creosote. The sodium fluoride has high toxicity, is not injurious to metal and is convenient to handle. Sap-pine ties were placed in the mines at Birmingham, Ala. in 1914, while red-oak ties were placed on the tracks of the Baltimore and Ohio railroad. After five years of mine service the ties treated with sodium fluoride were found in as good condition as those treated with zinc chloride. Both showed little deterioration. The creosoted ties were in better condition while untreated ties were in advanced stages of decay. The railroad

ties which were treated were practically all sound, while untreated ties had to be removed. Forest Products Laboratory, Madison, Wis. Address Director.

TABLE 3

Stage of Kiln run in hours.	Temperature, deg. Fahr.	Humidity, per cent.
1.....	120	100

**Wood Products A3-20 Wood Pulp with Decay.** Wood pulp infected with molds and fungi has been shown to be defective in producing dry paper, in requiring extra sizing, in sticking to couch and press rolls, and gives trouble from excessive foaming. Infected pulp is free in its action and causes difficulty in carrying the necessary amount of water. Infected pulp yields 10 per cent less finished paper than clean pulp, in addition to reducing strength of the finished paper. Forest Products Laboratory, Madison, Wis. Address Director.

**Wood Products A4-20 Shrinkage of Veneer.** The veneers made from steam logs, boiled logs were tested and found to contain about the same amount of moisture before drying (65 per cent) and about the same amount after drying (10 per cent). The shrinkage of each kind was about the same, variation being no greater than that found in the pieces from the same treatment. Forest Products Laboratory, Madison, Wis. Address Director.

**Wood Products A5-20 Moisture Content of Wood.** Moisture content of wood has been found to be independent of the density of the wood. With a relative humidity of 38 per cent at 80 deg. Fahr. in the oven the moisture content is about 11 per cent and with 88 per cent relative humidity the moisture content is 18.8 per cent. This is the same for specimens of varying densities. Forest Products Laboratory, Madison, Wis. Address Director.

#### B—RESEARCH IN PROGRESS

The purpose of this section of engineering research is to bring together those who are working on the same problem for co-operation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

**Aircraft B2-20 Wind Tunnels and Propellers.** The National Advisory Committee for Aeronautics reports a research in progress by means of models to determine the best form of wind tunnel and the best type of propeller to use in drawing the wind stream through the tunnel. Various arrangements are being studied, especially with regard to their power consumption for a given wind speed and to the steadiness of velocity and direction of air currents. Address Joseph S. Ames, of the Executive Committee of the National Advisory Committee for Aeronautics, 4th St. and Mission Ave., N. W., Washington, D. C.

**Cement and Other Building Materials B1-20 Compressive Strength of Concrete.** A paper is being prepared on the compressive strength of concrete based on the results of tests made by the Bureau of Standards at Lehigh University and Lafayette College in 1918 and at the Structural Materials Laboratory at St. Louis from 1904 to 1910. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Internal Combustion Motors B2-20 Ignition Apparatus.** The Bureau of Standards is being developing a mathematical theory of the building-up of voltage in the secondary winding after the opening of the primary breaker. Data from nine magneto have been received by the laboratory. The ratio of transformation and coupling coefficient has been determined and measurements of the mutual inductance are now in progress. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Materials of Engineering B1-20 Thermal Expansion.** A research in the determination of the thermal expansion for various substances. Several proposed outlines for the work have been drawn up. The work will keep the present laboratory force devoted to this subject busy for six months. Address Bureau of Standards, Washington, D. C. Address Director.

**Metallography and Metallurgy B3-20 Hardness Relations.** Relation of hardness, temperature of pouring and machining properties

of cast iron of given thickness and composition. Address Prof. W. W. Bird, Worcester Polytechnic Institute, Worcester, Mass.

**Properties of Engineering Materials B6-20 Strain-Gage Test.** A strain-gage test of the 350-ton fitting crane at the Philadelphia Navy Yard has just been made. The results of this test are to be made up in the form of a report. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Properties of Engineering Materials B7-20 The Use of the Camera in Studying Physical Properties.** The Bureau of Standards has been investigating photographic methods of studying elongations and lateral deformation of steel during tensile tests to determine the relation between elongation and lateral deformation. It is also developing a special camera for taking panoramic photographs of the interior of a gun barrel to study the effects of erosion. The lenses have been perfected and the camera is being constructed. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Properties of Engineering Materials B8-20 Insulating Materials.** The Bureau of Standards has carried on extensive investigations of the electrical and mechanical properties of insulating materials, giving particular attention to their behavior at radio frequencies. The research will include the effects of moisture and other tests to determine the practical usefulness of various materials. Special study has been made of bakelite and other materials of the phenol-methylene type, and materials such as glass, mica, celluloid, electrosite, paraffin, fiber, hard rubber, porcelain and wood will be included. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Properties of Engineering Materials B9-20 Physical Constants of Materials Used in Refrigeration.** The Bureau of Standards is investigating the physical properties of constants of materials used in refrigeration. The Bureau has recently determined the vapor pressure of saturated ammonia and densities of the liquid and saturated vapor. It has also determined the specific heat of sodium-chloride solutions. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Protective Devices B1-20 Carbon Monoxide Detector.** A. C. Fieldner, Supervising Chemist, U. S. St. J. Terrort, Physical Chemist, Bureau of Mines Station, Pittsburgh, Pa. So far the detector developed for gas-mask use by Lieutenant-Colonel Lamb and Captain Larson of the Chemical Warfare Service seems to be most promising. Bureau of Mines, Address Van H. Manning, Director, Washington, D. C.

**Railroad Rolling Stock and Accessories B1-20 Chilled-Iron Car Wheels.** Experiments are being made at the Bureau of Standards to determine temperatures at various portions of a wheel heated on the rim and to study the effects of this heating. Several wheels have already been tested at this plant. Work of a similar nature is being carried out at the University of Illinois. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

#### C—RESEARCH PROBLEMS

The purpose of this section of Engineering Research is to bring together persons who desire co-operation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring co-operation or aid will state problems for publication in this section.

**Textile Manufacture and Clothing C1-20 Drying of Thin Gauze on Tenting Machines.** The effect of humidity; the effect of velocity of air; the effect of heating cloth by radiation or by convection; the effect of drying selvages by installing steam pipes close to tenter fingers; best relative humidity of air at discharge for maximum drying rate. Address D. M. Ferris, Graduate Student, M.I.T., 37 Lee St., Cambridge, Mass.

#### D—RESEARCH EQUIPMENT

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

**Harvard University D1-20 Cryogenic Laboratory.** The equipment for the liquefaction of gases and for very low-temperature work includes two commercial air compressors for pressures to 3000 psq. in., and two commercial types of liquefiers as well as special apparatus which is under construction. In the Refrigerating Laboratory ammonia and carbon-dioxide compression plants are about complete.

The Internal-Combustion Laboratory is being equipped, although much of the apparatus for this laboratory has not been

purchased. Address Prof. Lionel S. Marks, Harvard University, Cambridge, Mass.

**Machine Tools D1-20** Cutting Action of Machine Tools. The University of Cincinnati is equipping its mechanical laboratory for the purpose of making investigations on the cutting action of machine tools. The university has recently received an Olsen efficiency-testing machine for files, milling cutters, lathe tools, hack saws and drills, and has also bought a number of Government machine tools to be used on research work. One of them is a large heavy-duty radial drill. A No. 3 planer milling machine will also be used for research work. The laboratory is to have a Charpy impact-testing machine and Olsen impact-testing machine and four Farmer fatigue-testing machines. Address Prof. A. L. Jenkins, University of Cincinnati, Cincinnati, Ohio.

**University of Cincinnati D2-20** Thermal Laboratory. The Mechanical Engineering Laboratory of the University of Cincinnati is equipped with an experimental gas engine made by the Foos Gas Engine Company, four small gas and oil engines, a 12 by 24-in. Hamilton Corliss engine, a Fairbanks gas producer and a number of automobile engines. Address Prof. A. L. Jenkins, University of Cincinnati, Cincinnati, Ohio.

#### E—RESEARCH PERSONNEL

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

**Purdue University E1-20** The Experiment Station at Purdue University is about to issue a bulletin on the use of electric power in small pumping stations, by Professor Ewing, and a bulletin on the Coefficient of Discharge of Sewage Sprinkler Nozzles, by Prof. W. W. Greve. Prof. O. C. Berry has nearly completed a bulletin on the Investigations of Carburetors and Prof. R. V. Achatz has completed a circular on the Effect of Preservative Treatment of Various Kinds of Telephone and Telegraph Poles. Address Purdue University, Lafayette, Ind. Dean C. H. Benjamin, Director.

#### F—BIBLIOGRAPHIES

The purpose of this section of Engineering Research is to inform the profession and especially the members of the A. S. M. E. of bibliographies which have been prepared. These bibliographies have been prepared at the request of members, and where the bibliography is not extensive, this is done at the expense of the Society. For bibliographies of a general nature the Society is prepared to make extensive bibliographies at the expense of the Society on the approval of the Research Committee. After these bibliographies are prepared they are loaned to the person requesting them for a period of one month. Additional copies are prepared which are available for periods of two weeks to members of the A. S. M. E. or to others recommended by members of the A. S. M. E. These bibliographies are on file in the offices of the Society and are to be loaned on request. The bibliographies are prepared by the staff of the Library of the United Engineering Society which is probably the largest Engineering Library in this country.

**Economics F1-20** Valuation of Street Railway Systems. A bibliography of 1½ pages. Search 2835. Address A.S.M.E., 29 West 39th St., New York.

**Hydraulics F1-20** Flow of Oil in Conduits. A bibliography of 10 pages. Search 2825. Address A.S.M.E., 29 West 39th St., New York.

**Metalurgy and Metallurgy F1-20** Microstructure of Electric and Acetylene Welds. A bibliography of 1½ pages. Search 2784. Address A.S.M.E., 29 West 39th St., New York.

**Petroleum, Asphalt and Wood Products F1-20** Flow of Oil in Conduits. A bibliography of 10 pages. Search 2825. Address A.S.M.E., 29 West 39th St., New York.

**Wood Products F1-20** Marine Boreers. A bibliography prepared by the Forest Products Laboratory, U. S. Forest Service, Madison, Wis. This contains eight references to articles and treatises. Forest Products Laboratory. Address Director Forest Products Laboratory, Madison, Wis.

## Unemployment, National Taxation and Profit Sharing

Reconciliation of the Needs and Demands of the Government, the Public, the Employer, and the Worker

By HENRY HESS, PHILADELPHIA, PA.

THE present disturbance in our industrial position has been a long time in the brewing. This process may be likened to a period of slow boiling under a gentle heat that gave the cook no serious cause for alarm, even though it did occasionally tilt the cover of the pot.

But let us leave this simile to concern ourselves with basic causes and see whether their recognition may not lead us to a basic remedy. It will be necessary to go back to the beginning of the modern industrial era and note the change which that brought about.

Under the older feudal system the subsistence of the working element was more or less well taken care of by the overlords or by the masters in the various guilds; and as long as these overlords and masters fulfilled their obligations, matters went along smoothly. It was only when these obligations were forgotten and the duty of providing subsistence was omitted that matters became serious. In other words, when subsistence became endangered the social economy became endangered.

When such subsistence becomes endangered under our changed conditions, then our modern social economy is in danger of similarly breaking down.

There are many changes in the relative situation of the modern worker as compared with his brother of bygone ages, but the basic interest is the same; the worker must be assured of his subsistence and of a subsistence of the improved character that the advance of general civilization and culture has brought about.

This is our problem today under our modern industrial system, as it has been the problem under the feudal system that has been displaced, and as it will be the problem under whatever future system may take the place of that of today, and so on to the end of time.

Now what one basic trouble stands out above all others? There are many minor ones that look large at the moment and large in the eyes of many; but which one applies to every man, woman and child worker? Unquestionably the fear that the means of subsistence may be withdrawn at any moment, which fear is the fear of unemployment. When we analyze the demand for increased wages we find that it resolves itself into the hope that the difference between increased and existing wages will permit the accumulation of a fund the interest of which will provide the basis for defraying the living cost during the recurring periods of unemployment.

The writer proposes to address himself to this problem, as he considers it the real problem, though frequently not definitely recognized as such; and to those others that are coexistent with it, such as the provision of the means for the maintenance of a proper government and all that that implies in activities that are best delegated to government. This then becomes the problem for our industrial system, since it is this which earns and creates wealth and then distributes it.

Men band themselves together in business organizations, which have gradually taken on the preferred corporate form; here capital and labor cooperate to increase the national wealth and to distribute it and to minimize the risks involved.

There are two groups in such corporations; one is generally

<sup>1</sup> 305 Bailey Building Past Vice-President Am.Soc.M.E.

Discussion prepared for the Industrial Relations Sessions at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, December 1919.

refered to as capital, the other as labor. The ideal grouping will equally divide the risks and responsibilities; and given such ideal grouping, the results or profits should be equally divided. Labor is today striving for such equal division, but is not yet willing to share equally the risk and responsibility. The more enlightened section of capital is willing to share with labor in proportion as labor fits itself to and does assume its share of the burden.

When that condition has been reached there will no longer be any problem that is basically serious; both sides will by then have forgotten such matters as unionism, the open shop, the closed shop, collective bargaining and whatever other standard people assemble under to wage industrial war and to inflict on one another the utmost injury of which they are capable; instead, they will mutually cooperate for mutually equal benefit.

Until that ultimate goal is reached man must live and live with

#### HYPOTHETICAL NATIONAL BALANCE SHEET<sup>1</sup>

Common Capital .....	\$50,000,000,000
Preferred Capital .....	10,000,000,000
Borrowed Capital (corresponds to Bonds; to receive 5% interest and be retired in 20 yr.) .....	30,000,000,000
Wages and salaries of 12,800,000 employees (exclusive of firm members), \$1060 per capita .....	13,568,000,000
Unemployment cost at 8% (approx.) .....	1,085,000,000
Gross income for 1917 (made up of Wages, Taxes, Interest, Dividends and Surplus for Manufacturing, Mining, Railroad and Public Utilities), \$1,926 per capita .....	\$24,653,000,000
Wages at \$1060 per capita .....	\$13,568,000,000
Bonded Indebtedness at 5% .....	1,000,000,000
Retirement of borrowings per yr. .....	1,000,000,000
Depreciation .....	500,000,000
State and Local Taxes, 2/3 of 1917 .....	17,068,000,000
Balance Net Earnings before Federal Tax .....	\$7,585,000,000
1st Charge—Income Tax (1917) .....	405,300,000
Balance .....	\$7,179,640,000
2d Charge—Cumulative Preferred Stock 6% .....	600,000,000 <sup>2</sup>
Balance .....	\$6,579,640,000
3d Charge—Plant betterment (= twice depreciation) .....	1,000,000,000
Balance .....	\$5,579,640,000
4th Charge—Profit Share 2% of Wage Bill <sup>3</sup> .....	271,360,000
Balance .....	\$5,308,280,000
5th Charge—Corporations' share to unemployment .....	\$13,640,000 <sup>2</sup>
Balance .....	\$4,494,640,000
6th Charge—Stockholders' Common share 4% dividend .....	\$2,000,000,000
1/2 as profit share .....	1,000,000,000
Balance .....	\$1,494,640,000
7th Charge—Excess Profits (2.3 of 1917 charge) .....	650,000,000
Corporations' Surplus Balance is 1.69% .....	\$844,640,000

<sup>1</sup> Based on year 1917.

<sup>2</sup> To be applied to labor's share to unemployment.

<sup>3</sup> Annual fixed charge if industry is shut down.

reasonable decency and must adequately subsist during those periodic disturbances in the orderly process of increasing individual and national wealth.

So far there are probably very few but agree with these general statements; but how carry them into effect? They have been and are being carried out here and there by small bodies and with entire success and consequent satisfaction to both sides.

If these few concerns gather followers in sufficient number to comprise the many that make up the nation, then the sporadic few would have become the complete whole. The balance sheets that are made up by the many individual concerns could then be gathered into one national balance sheet.

The writer has prepared such a hypothetical balance sheet as well as the insufficient data available permit. Unfortunately the

Government has not included collection of data covering unemployment in its census. Reliance must therefore be placed on such fragmentary information as has been collected by other agencies over certain sections of the country.

Unemployment is probably larger the denser the industrial population. Therefore, applying the conditions of New York City to the entire country will probably give a result that is in the nature of an overstatement and is in consequence safe for the liberation of funds to cover this unemployment cost.

A very careful census for New York City is available and published by the U. S. Department of Labor, Bureau of Labor Statistics in its Bulletin No. 172 in April 1915.

Averaging a table on page 10 of that bulletin shows that of all male and female workers 60 per cent were unemployed for 65 days, which corresponds to an average constant unemployment of 10.5 per cent.

The Federal Government had found it necessary to gather reliable data in connection with the collection of taxes. A brochure published by Prof. David Friday and entitled Profits, Wages and Industrial Progress, has furnished much information useful in the set-up of the hypothetical balance sheet prepared by the writer.

An examination of that sheet will show that all of the usual features carried in a condensed balance sheet are provided for, such as taxes of various kinds, plant depreciation and plant betterment that keep the industry in productive health, interest and repayment of borrowed capital, dividends on preferred capital with a sufficient surplus to return this preferred capital, ordinary dividends and such new features as provision for unemployment and profit sharing of capital and labor.

It is believed that these figures are entirely conservative, since the 1917 actual surplus was \$256.25 per capita or \$3,280,000,000, which is nearly four times the amount the above hypothetical balance sheet leaves as surplus. Ten per cent unemployment is equivalent to 9 years' surplus accumulation or (9 x \$844,600,000 =) \$7,601,400,000. Deducting from this the cost of one year's shutdown, \$1,413,640,000, leaves a balance of \$6,187,760,000, which corresponds to a dividend on common capital for 10 years of 12.37 per cent or per year of 1.24 per cent, this equity increasing the annual normal common capital dividend to 5.24 per cent.

#### RÉSUMÉ

The proposal suggests the removal of a very potent cause of labor unrest by insuring labor against the economic loss of involuntary unemployment through the accumulation of a fund. This fund is contributed to by labor, which applies a portion of its participation in general profits.

The Government's need for funds, over and above the amount raised by income tax, is covered by lending to the Government this unemployment fund.

It is possible to analyze or to set up a balance sheet showing the tangible quantities of the nation's business, but that method cannot be applied to the more intangible factors that are nevertheless the more important ones. Avoidance of the many consequences of unemployment and the fear of that will relieve the community of a very heavy burden and tend to an increased output of work willingly rendered by the worker, who is not only relieved of this fear of unemployment, but is also assured of a fair participation of the resulting profits.

The employer or capitalist finds his reckoning in the general stabilization of his business, which stabilization is of the same character as the assurance against unemployment.

The general public finds its interest given in the stabilization of business conditions generally and in the relief from the burdens of various kinds, financial and social, which it must carry as the result of unemployment.

The Government finds its advantage in there being placed at its disposition, for a period of years, an amount which it will therefore not have to raise by taxation, and this again will ease its public relations, as tax gathering is probably the most-objected-to feature of government.

## Work of the Boiler Code Committee

**THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.**

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in *MECHANICAL ENGINEERING*, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 267-272, inclusive, as formulated at the meeting of January 7, 1920, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

### CASE NO. 267

**Inquiry:** a Is it not permissible to form door openings in the furnaces of locomotive type boilers with the overlapping flanges riveted so that the heads of rivets project into the door opening? Is it advisable that these flanges be welded instead of riveted?

b Is there any objection under the rules of the Boiler Code to the use of baffles over the feed pipe discharge into the side of the barrel of locomotive type boilers?

**Reply:** a The projection of rivet heads into the door opening is not prohibited by the Boiler Code, although it is the recommendation of the Committee that in case the flanges are riveted the heads in the door opening be countersunk. Welding of the flanges is permissible under the rules of the Boiler Code, but there is nothing in the Boiler Code that indicates preference for either riveting or welding.

b Inasmuch as the use of the internal feed pipe is required only for h.r.t. boilers, there is no objection to the use of a feed-water baffle over the discharge of the feed pipe. It is, however, essential that the feed water shall not be discharged into the boiler, close to the riveted joints in the shell or to furnace sheets. (See Par. 316).

### CASE NO. 268

**Inquiry:** Inasmuch as the discharge of feed water into vertical fire tube boilers, in accordance with the requirement of Par. 316 of the Boiler Code, has caused serious difficulties from leaky tubes in the lower tube sheet, is it permissible to protect the feed water discharge through a feed water pocket riveted within the shell at a point above the water leg with handhole opening for cleaning.

**Reply:** It is the opinion of the Committee that such a method of delivery of feed water to the boiler is in full accord with the requirements of the Boiler Code.

### CASE NO. 269

**Inquiry:** If, under the provision made in Par. 212c of the Boiler Code, advantage is taken of the opportunity to increase the pitch of the staying for a cylindrical furnace, is it to be assumed that a portion of the increased load on the staybolt is to be supported by the resistance of the outer cylindrical shell to collapse, or must the staybolt be designed to carry the full load upon the stayed area of the furnace sheet?

**Reply:** It is the opinion of the Committee that the special provision made in Par. 212c for increased pitch, does not contemplate the division of the stress upon the stays, in view of the sup-

porting power of the outer cylindrical shell; it will not be permissible to increase the pitch under this rule, beyond the ability of the stays selected to carry the load.

### CASE NO. 270

(In the hands of the Committee)

### CASE NO. 271

**Inquiry:** Is it allowable under Par. 268 to utilize a flanged collar pressed into and flanged over the edges of the shell for a pipe connection, instead of riveting a flange to the shell, when the thickness of the plate is not sufficient to give the required number of threads?

**Reply:** It is the opinion of the Committee that such construction of pressed and flanged reinforcement for an opening in the shell, will be allowable under the requirement of Par. 268, for any pipe opening not exceeding 3 in. pipe size, provided the threaded portion complies with Par. 266 of the Code.

### CASE NO. 272

**Inquiry:** Is it permissible to form a dry pipe in a h.r.t. boiler by insertion of a 6 in. pipe threaded through a flange riveted to the rear head?

**Reply:** It is the opinion of the Committee that this connection of dry pipe is allowable provided: (1) That a flanged nozzle riveted to the head to receive a flanged fitting is employed; (2) That the dry pipe is detachably connected to the nozzle; (3) That the dry pipe is properly supported.

## CODE FOR BOILERS OF LOCOMOTIVES

In the August 1919 issue of *MECHANICAL ENGINEERING* (page 682) there was published the preliminary report of the Subcommittee of the Boiler Code Committee on Boilers of Locomotives, which is proposed as Part I, Section III of the Code. This report was the result of over two years careful investigation and study by this Subcommittee and the report was first submitted to the membership of the Society at the spring meeting at Detroit, Michigan, in June 1919. The report was accepted by the meeting and ordered published. Following the publication in August 1919, arrangements were made in accordance with the established practice of the Boiler Code Committee, for a public hearing on this question, which was held during the business session of the Annual Meeting on December 3rd, 1919, in order that all interested parties might be given an opportunity to discuss any feature of the requirements in the proposed Code.

As a result of the hearing and the discussion, which lasted into the following day, December 4th, recommendations were accepted from the hearing, which resulted in the following revisions in the preliminary report. They are here published for the information of the membership. Anyone desiring to discuss the changes here proposed is requested to address the Secretary of the Boiler Code Committee, 29 West Thirty-ninth St., New York, N. Y.

## Revisions of Preliminary Report on Boilers of Locomotives

*Not Subject to Federal Inspection or Control*

Based on Report as published in *MECHANICAL ENGINEERING* (Journal of the American Society of Mechanical Engineers), August, 1919, page 682.

## PAR. L-2:

CHANGE WORDS IN SECOND LINE AS FOLLOWS:

excepting from tube sheets — to read — excepting front tube sheets.

## PAR. L-18:

CHANGE HEADING OF TABLE 2 TO READ AS FOLLOWS:

Gage thickness of walls of fire tubes

## PAR. L-20:

CHANGE PARAGRAPH TO READ AS FOLLOWS:

The maximum allowable working pressure is determined by employing the factors of safety, stresses and dimensions designated in these rules.

The factor of safety used in design and construction of new boilers shall not be less than 4.5.

The factor of safety used in determining the maximum allowable working pressure calculated on the conditions actually obtaining in service shall not be less than 4.0.

The maximum allowable working pressure determined by conditions obtaining in service shall not exceed that for which the boiler was designated.

No boiler shall be operated at a higher pressure than the maximum allowable working pressure, except when the safety valve or valves are blowing, at which time the maximum allowable working pressure shall not be exceeded by more than 5 per cent.

## PAR. L-21:

ELIMINATE LAST SENTENCE, WHICH READS AS FOLLOWS:

For new constructions covered in Part III, FS in the above formula = 4.

## PAR. L-27:

ELIMINATE ENTIRE PARAGRAPH.

## PAR. L-28:

RENUMBER THIS AS PAR. L-27.

## PAR. L-29:

RENUMBER THIS AS PAR. L-28.

## PAR. L-29:

INSERT NEW PARAGRAPH AS FOLLOWS:

Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code and when the safety of the structure is not dependent upon the strength of the weld.

## PAR. L-30:

REVISE LAST SECTION OF PARAGRAPH TO READ AS FOLLOWS:

When boiler shells are cut to apply steam domes or man-holes, the net area of metal, after rivet holes are deducted, in flange and liner, if used, must be not less than the area required by these rules for a length of boiler shell equal to the length removed. A height of vertical flange equal to three times the thickness of the flange shall be included in the area of the flange.

## PAR. L-31

CORRECT FORMULA TO READ AS FOLLOWS:

$$P = C \times \frac{t^2}{p'}$$

## PAR. L-32:

CHANGE FIRST LINE OF SECOND SECTION TO READ AS FOLLOWS:

Staybolts behind permanent brickwork, frame braces, or grate bearers.

## PAR. L-52:

ADD NEW SECTION TO THIS PARAGRAPH TO READ AS FOLLOWS:

The ends of arch tubes must be belled out to a diameter  $\frac{1}{4}$  in. larger than the hole in the sheet to which they are connected.

## PAR. L-58:

ADD NEW SECTION TO THIS PARAGRAPH TO READ AS FOLLOWS:

If, in any longitudinal section of an unstayed plate, more than two holes are so located that the strength of the ligament between them is reduced below the strength of ligament of the longitudinal seam, the plate must be reinforced to maintain the strength through that section.

## PAR. L-60:

CHANGE LAST SENTENCE TO READ AS FOLLOWS:

than five per cent. above the specified boiler pressure.

## PAR. L-73:

CHANGE FIRST LINE TO READ AS FOLLOWS:

Each boiler shall have at least one water glass provided with top and bottom shut-off cocks, and lamp

ALSO ADD NEW SECTION TO READ AS FOLLOWS:

Tubular water glasses must be equipped with a protecting shield.

## PAR. L-75:

CHANGE LAST WORD TO READ "ENGINEMEN."

## CORRESPONDENCE

**C**ONTRIBUTIONS to the Correspondence Departments of MECHANICAL ENGINEERING by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

## The Value of Sheet Asbestos on Hot Pipes

## Comments on Contribution in January Number

## TO THE EDITOR:

In notes on research, entitled Value of Sheet Asbestos on Hot Pipes, by Mr. T. S. Taylor, published in a prominent place in the January issue of MECHANICAL ENGINEERING, certain statements were made which, while entirely true in themselves, have been subject to considerable misconception.

There is nothing new or remarkable in the fact that a bright galvanized-iron surface will radiate heat at a much slower rate than a dull mat surface. Therefore, it is not surprising that placing over the bright surface a very thin layer of asbestos paper should increase the radiation. The paper was only a little over 1/100 in. thick, which is so thin that it could have but little insulating value, and the net effect was mainly the change in the character of the radiating surface and consequently the rate of radiation.

It should be borne in mind, however, that the high surface

resistance to heat flow presented by a bright surface decreases rapidly as the surface becomes tarnished or if it is painted. Therefore, the radiation from such surfaces becomes much greater.

The principal cause for mistaking the true significance of the statements was the failure on the part of the average reader to distinguish between mere asbestos paper and asbestos insulation. This distinction was not mentioned in the article and it has been but natural that the casual reader should attribute to asbestos in general the poor results shown by the test for very thin asbestos paper.

The contribution is an arraignment and rightly so of the practice of covering furnace pipes with a thin layer of asbestos paper. The belief has been too prevalent that pipes covered with "asbestos" were properly protected, regardless of the thickness or quality of the asbestos. Therefore, instead of indicating any lack of usefulness of asbestos, the results of these tests properly interpreted bring out more forcibly the need for sufficient thickness of proper insulation.

New York, N. Y.

L. B. McMILLAN.

## TO THE EDITOR:

I read with some concern an article in the January number of *MECHANICAL ENGINEERING*, page 69, on the value of sheet asbestos on heat pipes. This fact was reported in a paper read by the writer at the June 1919 meeting of the National Warm Air Heating and Ventilating Association, and has since been given wide publicity. I am therefore surprised to see this article appear.

It is interesting to note that the results obtained by this investigator agree very closely with the results reported by the writer in the proceedings of the meeting mentioned above. His work certainly serves to clinch our argument against the use of asbestos-paper covering on heat pipes.

I am sending under separate cover a copy of a paper by Prof. A. C. Willard, of the University of Illinois, *Mem. Am. Soc. M. E.*, dealing with our testing program for warm-air furnaces. It contains some data on our tests of insulating materials for heat pipes, and the other information contained may be of interest to you.

Urbana, Ill.

V. S. DAY, Research Assistant,  
University of Illinois.

In the report referred to by Professor Willard results are given of measurements made by Mr. Day of the temperatures across the air currents in a tin leader running from a hot-air furnace. Temperature traverses were made in a 10-in. leader of bright tin and in the same leader covered with one layer of asbestos paper weighing 10 lb. to the 100 sq. ft. These tests showed that the asbestos-paper-covered pipe lost heat more rapidly than the bright tin pipe, a fact which led to subsequent experiments on the heat lost from covered and uncovered pipe.

TABLE 1 RELATIVE HEAT LOSSES FROM THIN SHEET METAL PIPES WHEN COVERED AND UNCOVERED

Description of Drum	Wt. Steam Condensed in 10 hr.	Coeff. of Emissivity
1 Bright 1 C tin, 1 leader section.....	11.63	1.40
2 Same as No. 1, but covered with one sheet 10 lb. asbestos paper.....	17.80	2.30
3 Same as No. 2, but painted with gray enamel..	18.14	2.32
4 Same as No. 1, but painted with gray enamel, as in case No. 3.....	18.88	2.40
5 Black iron, No. 28 U. S. gage.....	18.29	2.25
6 Galvanized iron No. 28 gage.....	11.72	1.55
7 Same as No. 1, but covered with 8-ply air-cell asbestos paper.....	5.86	0.70
8 Same as No. 1, with 5/16-in air space made by double wall of tin.....	6.32	0.78

For this purpose a special heat-transmission plant was built, supplied with low-pressure steam. Sheet-metal drums, all of the same size, were used in determining the heat loss. Five drums were tested at one time, with a sixth drum operated as a control in order to maintain uniform conditions. A few of the more interesting results are given in Table 1. In this table the "coefficient of emissivity" is based on the temperature difference, steam to air (steam pressure maintained at  $1\frac{1}{2}$  in. of mercury), and gives the loss in B.t.u. per sq. ft. of surface per hr. per deg. Fahr., temperature difference.

As in the case of the tests by Mr. Taylor referred to in Mr. Day's letter, there was a large increase in heat loss when the metal was covered with a single thickness of asbestos paper without air space to retard the transmission of heat. Superior results were obtained, however, with air-cell asbestos paper and with a leader having a double wall and air space between, as shown in Tests Nos. 7 and 8 in Table 1.—[EDITOR.]

## TO THE EDITOR:

It has been brought to the writer's attention that some readers of his notes on the above subject, contributed to the January issue of this magazine, have obtained very incorrect ideas concerning the proper interpretation of the results there given. Numerous letters relating to this contribution have been received,

but so far no one has given incorrect impressions of the results. The writer has learned indirectly, however, that some readers have interpreted the results to mean that since a little asbestos is a poor thing on hot-air pipes, more asbestos would be even worse. It is a little difficult to see how any one in reading the notes can come to such conclusions. While it is specified clearly that a thin layer of asbestos on hot-air pipes promotes the loss of heat to the extent of 33 per cent more than if the pipe was left bare, it is also made clear that three layers of thin asbestos 0.013 in. thick applied loosely will make the loss from the covered pipe the same as from the bare pipe; and furthermore it is pointed out that if the layer of asbestos is sufficiently thick, about  $\frac{1}{8}$  in., the loss through the covered pipe will be only 75 per cent of that through the bare pipe, thus resulting in a saving of 25 per cent. A thicker layer will cause even a less loss. This statement cannot be taken to hold indefinitely for various sizes of pipes, but it does hold within limits for pipes of such dimensions as 9 in. to 10 in. in diameter.

The reason why more heat will pass through a pipe when covered tightly with thin asbestos than when bare is that the effective area of the pipe as far as molecular dimensions and motions are concerned, is increased at least some two or three times by the layer of asbestos, while the thermal resistance due to the layer of asbestos is quite small. The result is that more molecules can come into close contact with the surface, and thus having their kinetic energy or temperature increased, more heat will be carried away. This increases the loss due to conduction and in particular that due to convection, which is the principal method by means of which heat is liberated at the temperatures here dealt with. The extra loss is thus due to the increase in molecular contacts and not to the difference in the radiating power of the two surfaces. Radiation at the temperature differences dealt with in furnace-pipe surfaces plays a very insignificant part in the loss of heat.

Now, since the effective molecular area of the surface of the pipe is so much increased by the asbestos surface over that of the smooth pipe, it is necessary to add enough asbestos or heat-insulating material to cause a temperature drop through this insulation so as to have its external surface at a considerably lower temperature and thus reduce the loss from the outer surface. Thus, if the layer is sufficiently thick the temperature of its outer surface will be low enough to overcome the advantage gained, as far as heat loss is concerned, by the rough surface. Consequently, in order to protect pipes, meet fire-insurance regulations, and also save loss of heat, hot-air pipes should have a much thicker coating of insulating material than is at present applied. This can be a thicker layer of asbestos, several layers of thin sheet asbestos, asbestos air-cell paper or any suitable material used for this purpose.

Pittsburgh, Pa.

T. S. TAYLOR.

## The Correct Statement of Averages

## TO THE EDITOR:

While agreeing with Mr. Hess that an arithmetical average is very apt to be misleading (page 955, December *MECHANICAL ENGINEERING*), I do not feel sure that the mere statement of maximum and minimum figures is sufficient indication of the degree of reliability achieved.

Personally, I have found my own graphical method, which was described on page 226, vol. 104 of *Engineering*, the most reliable one I know, since it eliminates data which are obviously out of accord with those most often obtained in a series of experiments.

London, England.

C. H. WINGFIELD,  
M. Inst. Mech. E.

The Swiss Economic Mission expects to sail on May 7, 1920, for a forty-two days tour of this country to study the general economic conditions. A delegation of about sixty engineers from the Mission will probably be in St. Louis at the time of the Spring Meeting.

## "Industrial Unrest" Not an A.S.M.E. Pamphlet

With other members of the Society, the signers of this statement have received an anonymously written and distributed pamphlet entitled "Industrial Unrest," bearing the seal of The American Society of Mechanical Engineers and mailed with a New York City return address.

Inasmuch as we have been individually and officially active as members of the Executive Committee of the Metropolitan Section in bringing the subject of Industrial Relations before the Society, we feel compelled publicly to disclaim any connection with or knowledge of this publication.

We deplore the issue of this anonymous booklet bearing the imprint of the Society's emblem. Not only do we consider that an improper use has been made of the Society's emblem, but we resent the discourtesy to the Council of our Society perpetrated in sending out such propaganda on a subject that is now before the Council for action and on which a special committee appointed by the Council is soon to report.

## History of the Students' Army Training Corps

A review of the activities of the Committee on Education and Special Training has been published by the War Department. This records the history and general operations of the Students' Army Training Corps over which it had supervision from its inception on Feb. 10, 1918, until the completion of the settlement of the contracts made with colleges on June 30, 1919.

The report gives interesting information as to the personnel of the staff, the educational methods of intensive training in both vocational and collegiate divisions, the types of schools and equipment, costs, specialization curricula, rating and testing, course specialists, teachers, and the war-issues course.

Brig.-Gen. R. I. Rees was chairman of the Committee; Lt.-Col. Grenville Clark, secretary and executive officer. The activities were conducted by three major departments—the educational, the military and the business. The educational department was subdivided into three departments. Mr. C. R. Dooley was director of the vocational training division, the late Dr. C. MacLaurin, director of the collegiate training division, and Dr. Frank Aydelotte, director of the war aims division. The business administration was under the direction of Mr. E. K. Hall.

The Civilian Advisory Board included Dr. C. R. Mann, chairman; J. W. Dietz, secretary; Dr. J. R. Angell, Dr. S. P. Capen, Mr. Hugh Frayne, Dr. R. A. Pearson, Dr. Herman Schneider.

The demobilization of the S. A. T. C. was ordered on Nov. 23, 1918, and over three hundred thousand student soldiers in 630 educational institutions were returned to civilian status before Christmas, 1918.

## Engineering Organization in India

The Indian Industrial Commission, which was appointed to consider the development of engineering works and industries in India, included in its report a recommendation of the formation of a Society of Indian Engineers which should include all branches of engineering. Last December, at a representative meeting of engineers held in Calcutta, the formation of such a Society was realized. All the existing organizations in India have decided to incorporate in the new Society.

Engineering Society developments in India have been interesting. In a vast country like India where the engineers are separated by great distances, exchange of experience and access

## Spring Meeting of Mechanical Engineers at St. Louis

The attention of mechanical engineers is called to the Spring Meeting of The American Society of Mechanical Engineers to be held at St. Louis May 24 to 27. Two of the leading sessions will be devoted to subjects of local interest, although of national importance, those of the development of transportation on the Mississippi River, with a view to shipping products to foreign countries by water by the lower Mississippi and the Gulf of Mexico, and the other on recent developments in industrial housing in which there is a large project under way at St. Louis.

There will be papers on fuels, oil engines, measurement of the flow of water, transmission of heat, pumping engine tests, airplane design, supercharges for aeroplane engines and performance of automobile trucks, etc. All authors who expect to contribute papers are asked by the Committee on Meetings and Program to send their manuscripts to the Society by March 15. It is expected that the program of the meeting will be published in the April number of MECHANICAL ENGINEERING.

## A.S.M.E. Members in Second Pan American Financial Conference

That engineers are steadily coming to the front in the discussion of national and international problems was once again evidenced by the number of A. S. M. E. members who participated in the deliberations of the Second Pan American Financial Conference, which was in session in Washington for 10 days beginning on January 19. The Conference was attended by ministers of finance and other delegates from each of twenty Latin-American countries and representatives of the United States appointed by the Secretary of the Treasury. Among the leading Americans chosen were the following members of The American Society of Mechanical Engineers: Arthur L. Church, for Bolivia; Maurice Coster, for Colombia; Andrew Fletcher, for Chile; Hollis Godfrey, for Peru; John Hays Hammond, for Chile; George H. Harries, for Salvador; E. M. Herr, for Ecuador; Ira N. Hollis,

to libraries is difficult and various efforts have been made to overcome these disadvantages.

It has been realized that the Government of India might on many occasions derive advantage if there were a recognized corporate body, representative of the engineering profession, which might be consulted upon such subjects as the education and training of engineers, the grants of concession for mining rights or water-power, the regulation of electrical supply undertakings, etc. The new Society of Indian Engineers hopes to be able to assume the responsibilities which would fall to such an organization.

### Gift of \$5,000,000 for Promoting Research

The Carnegie Corporation of New York has announced its purpose to give \$5,000,000 for the use of the National Academy of Sciences and the National Research Council. It is understood that a portion of the money will be used to erect in Washington a home of suitable architectural dignity for the two beneficiary organizations. The remainder will be placed in the hands of the Academy, which enjoys a federal charter, to be used as a permanent endowment for the National Research Council. This impressive gift is a fitting supplement to Mr. Carnegie's great contributions to science and industry.

The National Research Council is a democratic organization based upon some forty of the great scientific and engineering societies of the country, which elect delegates to its constituent divisions. It is not supported or controlled by the Government, differing in this respect from other similar organizations established since the beginning of the war in England, Italy, Japan, Canada and Australia.

All are familiar with the great achievements in research which have been accomplished in Germany; but in that country research has been backed and controlled almost exclusively by the government, banks and a few large firms and organizations closely allied to the government, and it was these same firms and government which have mainly benefited by the results of the research. The objectionable features of the autocratic régime of the country have been carried into the organization of the research work and have materially affected the handling of its results.

The National Research Council hopes to achieve scientific results at least comparable to those which the Germans have achieved, and to accomplish this by democratic methods in consonance with the spirit of this country and to create a movement toward research work that may ultimately become general among small as well as large organizations. It is intended that the work shall become so coördinated as to make the results beneficial to the industrial life of the country generally rather than to a few large concerns, and thus stimulate economic research throughout the nation.

The National Research Council was organized in 1916 as a measure of national preparedness, and its efforts during the war were mostly confined to assisting the Government in the solution of pressing war-time problems involving scientific investigation. Reorganized since the war on a peace-time footing, it is now attempting to stimulate and promote scientific research in agriculture, medicine and industry, and in every field of pure science. The war afforded a convincing demonstration of the dependence of modern nations upon scientific achievement, and nothing is more certain than that the United States will ultimately fall behind in its competition with the other great peoples of the world unless there be persistent and energetic effort expended to foster scientific discovery.

### Proposed National Labor Program

The three parties commonly regarded as closely related to the labor problem are the worker, the employer and the public. Mr. Henry Hess in this number (p. 185), recognizing that the problem is national in scope, proposes to add a fourth party—the Government—and advances a cooperative plan for reconciling the needs of all four. In this case, however, the role of the Govern-

ment is not to be its usual one of adjuster of labor difficulties, but it is to play a more helpful and constructive part.

Mr. Hess believes that the trouble with labor is its inability to meet living expenses continuously; to save up against a day of unemployment and to accumulate funds against the period of old age. There are other issues, of course, but he holds that the fear of unemployment is basic.

On the other hand, he considers that an ideal condition would exist if labor and capital should divide equally their risks and responsibilities and share equally in the profits of industry. While this ideal is far from being reached, a few firms and their employees have advanced a long way toward this goal; and he feels that if such mutual cooperation should become general the groundwork would be prepared for a national plan whereby the demands, not only of capital and labor, but also of the public and the Government might be met.

His plan includes profit-sharing and provides for the accumulation of an unemployment fund to which labor would contribute a part of its share of the profits. The fund would be lent to the Government which would thus have placed at its disposal sums which it would not have to raise by taxation. Labor would benefit through ease of mind and insurance against time of need. Capital would benefit through stabilized business. The public would benefit for the same reason and because relieved of its burden of caring for the unemployed.

The engineering method in industry involves a study of facts and the formulation of a working plan before attempting to proceed with the work. In this proposal Mr. Hess has applied the engineer's method to a great economic problem, tempering it, however, by a recognition of the human characteristics involved. The proposal may or may not be practicable, but it is an attempt to solve a pressing national problem and so of timely interest.

### Are Prices Coming Down?

The industry of the country has been built up during the last few years on the idea of high wages, high prices of raw materials, and high prices of manufactured products. Many devices of production have been adopted in order to operate economically under such conditions as were created by war demands and war shortages. There are various indications, however, pointing to an impending change in economic conditions. Some of these are quite faint as yet, while others are fairly plain to all who would read.

A careful analysis of the situation, given by *The Annalist* (Monday, Feb. 9, 1920), would indicate that the long expected fall in prices may be at hand. This view is based on considerations of events in the commodity and security markets. Cotton, corn, pork, lard, and other commodities were marked down substantially under dealings at Chicago, and there was also a material fall in the prices of stocks. It is also influenced by the fall in European exchange and consequent decrease in the export of commodities. *The Iron Trade Review* (Feb. 12, 1920) gives important facts which bear very materially on the same situation.

The difficulties of exchange have affected the situation in two ways. In the first place, foreign purchasers find the prices of American goods at the present rates prohibitive and are making shifts to do with as little imported goods as possible. A number of projects in which American raw materials and machinery were to have been used have been discontinued, and in other projects orders were placed where the exchange situation was less difficult than in the American market. Thus, it has become known that a large order for locomotives which was to go to an American concern was placed in England.

The same exchange difficulties have brought about a situation where banks refuse to accept bills based on sales abroad, except for collection only, which means that the concern selling abroad has to furnish its own capital to handle the transaction. Considering the length of time which must elapse until a transaction is completed and paid for, this situation imposes an excessively severe hardship on the exporter. *The Iron Trade Review* cites a case where a \$5,000,000 sale of iron and steel goods to an

Italian customer broke down in face of such a requirement on the part of American bankers.

The same situation affects the export of foodstuffs. Not only can American foodstuffs not be exported in the face of a 25 per cent handicap on the exchange, but European foodstuffs, such as Danish butter, are finding their way to United States ports.

At the same time it should be clearly realized that so far the fall of prices has mainly affected articles in which there has been no domestic shortage, and of which the prices have been maintained either by sales abroad or by storage holdings for foreign markets actually or prospective. Where the article is such that there is or is likely to be a serious domestic shortage prices are not only not coming down but have an upward trend. Such is largely the case with steel, and fuel oil and its various products.

On the whole it would appear that the trend of business affairs has clearly begun to favor the consumer, who, however, has no way of estimating just how far this will extend. The consumer sees the beginning of price recessions and an active demand which may be stimulated by lower prices, and the manufacturer has to view the same situation. The question is how these forces will act in relation to one another.

### Aeronautics in the United States

The impression appears to prevail that the state of aeronautics in America, as compared with that in Europe, is decidedly backward and in every way inferior. Developments on the two continents have been compared to the disadvantage of this country, both in regard to technical achievement and the government appropriations for aviation work.

The actual situation, however, from an American point of view, is far less disturbing than would appear. As regards appropriations, the situation is not good either here or abroad, although probably a good deal worse here than in Europe. The original appropriations in England and France were enormous, the appropriation in England being more than \$300,000,000 for one year; but these appropriations have been very greatly cut down, partly because of the tendency to economize and also because of the growing feeling that important changes, mechanical and otherwise, in the aeronautical field are impending and that it might be well to await developments before incurring expenditures of such large sums.

In this country Congress has refused to appropriate any considerable sum for the present, and, in this respect, the situation is anything but encouraging.

The development of commercial aviation abroad has been of a more startling character and much better advertised than here. Thus, practically regular communication is maintained between London and Paris and a few other large cities. This is cited as showing the progress of aviation abroad. On the other hand, regular communication by aeroplane has been maintained in this country between New York and Washington for many months and is now being extended to Chicago. Our Forest Service is employing aeroplanes with great effectiveness for the detection and combating of forest fires. On the Pacific coast power transmission companies use aeroplanes to locate and repair faults and breaks in transmission and telephone lines, especially in the mountain regions. Ranchers find communication through the air a great boon in inspecting widely scattered herds of cattle and sheep over trackless ranges where an automobile is often of little service. In Texas, oil men have also found the aeroplane of great advantage, both in inspecting widely scattered properties and in quickly reaching new fields where indications of liquid wealth have been located.

It would be fair to state that from the point of view of organization and results achieved the American developments are, if anything, carried out on a greater scale than the European.

In the field of straight commercial aviation the United States probably leads. Thousands of planes are already in use by the public for every-day commercial work and such large companies as, for example, the Curtiss, are literally working day and night and still have considerable difficulty in keeping up with the orders accumulating on their books. An encouraging feature is

that a number of American aeroplanes and aeroplane parts have been sold or contracted for abroad, especially to South America, South Africa and China.

Comparing the number of aeroplanes sold to the public in their dollar value, America again leads. In making such a comparison it should be noted that only a very small number of war planes have been sold to the public and that the largest number of planes going for public use have been those built since the armistice and designed for peace purposes, a situation which is more favorable in every respect than that existing in Europe, where it is chiefly the discarded war planes which go for purposes of commercial aviation.

In this connection, rather significant statements have been made in British aeronautical papers in reference to the situation existing in Scandinavian countries. The conditions there favor the adoption of aeroplanes for communication between the islands in the North Sea and the inter-country and a considerable number of German planes were bought for this purpose. This was followed by a large number of accidents fatal and otherwise and when we learn that German discarded war planes have been bought with an extra engine for about \$100 American dollars, it is very easy to conceive why their use has proved disastrous to aviators.

There have been several important technical developments in America to which the general public has not paid the attention deservedly due. One of the most significant of such developments was the tests carried out by the Navy Department, in connection with the Martin torpedo plane. This plane exceeded by far the requirements set by the Navy Department for its adoption and actually carried a torpedo weighing in excess of half a ton at a speed of 120 m.p.h. In fact, the results of these tests have been so encouraging as to point to the possibility of the torpedo plane entirely revolutionizing marine warfare. The torpedo plane is entirely an American invention and was proposed many years ago by a member of the American Navy.

Another important development has been refinement in the design and operation of the Liberty motor. In the months which have elapsed since the armistice a large amount of valuable work has been done on this motor whereby it has been brought to a high state of efficiency. The Liberty motor of today stands out as one of the great achievements of American engineering genius.

The wireless telephone for use in aviation is practically exclusively an American development and in the last year has been brought to an unusually high state of perfection.

In addition to these the most earnest consideration should be given to the important results achieved during the last two years in such research laboratories as McCook Field and the U. S. Bureau of Standards. Under the impetus of war and partly on funds provided by Congress during that period, a large number of important investigations on the stress of materials, fuels, electrical equipment of aeroplanes, etc., have been carried out, and now the American manufacturer of aeroplanes and accessories has a vast fund of information at his command; and what is, perhaps, more important, a number of men who have carried out investigations are cheerfully ready to give of their fund of knowledge to those wishing to use it in a legitimate way for the good of the country.

---

The first copy of *The Tech Engineering News*, published by the undergraduates of the Massachusetts Institute of Technology, has just been issued. It is a 16-page journal, 9 by 12 in. in size, published monthly, and its purpose is to provide a medium for the exchange of ideas between the Institute (the faculty, undergraduates and laboratory workers) and men of executive rank throughout the country. Its articles are intended to be of a character to interest practicing engineers as well as students, and to acquaint each with the needs and conditions of the other. The first issue contains a number of original articles of merit; some of them are strictly of a technical character, presenting new material, while others deal with the business side of the engineer's work, as in one contribution upon Possibilities for Civil Engineers in South America.

## American Engineering Standards Committee Actively Engaged in Organizing Standardization Work

The American Engineering Standards Committee, organized in 1918 by representatives of the national engineering societies to secure coöperation and prevent duplication in the work of standardization, now has a revised constitution, with by-laws and rules recently adopted by the coöperating societies. These are of wide scope and allow the direct or indirect participation of any organization interested in standardization. Provision is made for direct representation on the Committee of additional organizations or groups of organizations.

The Committee's activities are already taking on an international character. It has approved specifications for standard pipe threads, for which The American Society of Mechanical Engineers and the American Gas Association are sponsors, and are representing America on this subject at an international conference in Paris. Coöperation is in progress with the National Screw Thread Commission, by which direct coöperative work with the British, not possible by the official Commission, is being carried out. The Committee is also in active coöperation with the Canadians on bridge specifications, with the British on specifications for machine tools, and with the Swiss on specifications for ball bearings.

A large conference, in which practically all national organizations interested in industrial safety participated, has unanimously voted that all industrial safety codes should be prepared under the auspices of the American Engineering Standards Committee. This was reported in the February number of MECHANICAL ENGINEERING.

### HOW THE COMMITTEE OPERATES

Any organization may request the Committee to approve standards which it has formulated, or to approve committees that it has appointed, and by so doing becomes a sponsor society. Two or more organizations may act as joint sponsors. Approval of the standard is given when it is the substantially unanimous conclusion of a section committee made up of representatives of producers, consumers and general interests, and so selected that all interests concerned have adequate representation on the section committee.

It is understood that a standard must be referred to as that of the sponsor, using whatever title the sponsor has given it, followed by the statement—"Approved by the American Engineering Standards Committee." The approval may be given in one of three ways: "Recommended Practice," "Tentative Standard" or "American Standard." The "approval" of a standard does not mean that the Committee has itself worked over and approved each detail, but rather that the work has been carried out by a sectional committee adequately representing the industry concerned, and sponsored by one or more bodies of ability, experience and standing, so that the result may stand for what is best in American engineering practice.

Any standard or group of standards adopted by any organization or in process of preparation, prior to January 1, 1920, may be approved by the Committee, if in the opinion of the Committee it has either been developed by a properly constituted committee, or has, by actual practice, proved its right to become a standard.

In addition to the work of assistant in the selection of committees and certifying that their work has been done under proper conditions, the Committee will act as a bureau of information regarding standardization.

### PERSONNEL OF COMMITTEE

The Committee as it exists today consists of 24 members and includes representatives of the American Society of Testing Materials and of the Government Departments of Commerce, Navy and War, as well as of the founder Societies. Its former

chairman, Prof. Comfort A. Adams, who has done painstaking work for the Committee since its inception, has been obliged to retire from this office because of the press of other affairs, and he is now succeeded by A. A. Stevenson, Past-President of the American Society for Testing Materials. Its secretary is Dr. P. G. Agnew, formerly of the U. S. Bureau of Standards, with headquarters in the Engineering Societies Building, 29 West 39th Street, New York. Until recently when it was possible to arrange for a permanent secretary, Prof. C. B. Le Page, secretary of the Standards and Technical Committees of the A. S. M. E., acted as volunteer secretary.

## PROPER BALANCING OF FUEL, LUBRICANT AND MOTOR

(Continued from page 168)

will be entirely consumed on top of the pistons. Effecting compression of the air and gasoline outside of the cylinder, and igniting the charge upon admission and during the power stroke, would overcome practically the entire amount of fuel-and-air-mixture leakage that takes place during the compression stroke of the present four-cycle motor. Other methods will undoubtedly be proposed and worked out successfully as soon as the seriousness of the present situation is fully established.

### CONSERVATION OF LUBRICATING OIL AND FUEL

In the Air Service during the war the necessity existed for the conservation of lubricating oil, and a simple system of reclamation was designed and placed in the thirty flying fields in this country which brought about a considerable saving in oil and money. The records show that 40 per cent of the oil issued and used in the aeronautic engines was sent back to the reclaimers, and of that amount 73 per cent, and as high as 95 per cent, was reclaimed and made available for reuse, and the test records show that this reclaimed oil was, if anything, a better lubricant than the original new oil. The engines were cleaner after its use, 50 per cent of the field flying engineers stated the reclaimed oil was preferred to new oil; the other 50 per cent said it was just as good as new oil.

Oil reclaimers are commercially successful. It is only necessary to have steam for their operation. They should be installed in every commercial garage. Reclamation of motor oil can be carried on without trouble and at a cost not exceeding ten cents a gallon. The oil so reclaimed will be just as good a lubricant as when new, but will be dark in color and have a slightly burnt odor, correction of which will require expensive and elaborate equipment and is not at all necessary.

Where reclaimers are installed oil should be removed every day. Motors should be made with larger drains and with easy methods of draining and filling. In fact, it should be as easy to drain and fill a modern motor with lubricating oil as it is to fill the radiator with water or the tubes with air.

Devices to remove the dilution in the oil in the motor or in the reclaimer do not solve the main problem of economy of use of gasoline. This is squarely up to the motor manufacturer or the designing engineer. The solution must come through some entirely different mechanical use of the fuel.

Then the importance of the care of gasoline and lubricating oil must not be overlooked, and the needless wasting of even the smallest amount of gasoline or oil per car must be avoided.

We are dealing with a disappearing asset. The Bureau of Mines has sounded repeated warnings as to the reducing reserves. The oil age which we are now living in will be shortened if we do not conserve our supplies by every possible means, and conservation is squarely up to the engineers of the country, as it is necessary first to secure engines that will utilize more of the heat units of the fuel, and are so designed that mechanical losses in the use of the fuel will not occur. And it is up to the millions of car users to prevent the small losses per car which in the aggregate mean million of gallons of a product which is of prime necessity to modern industry.

# Herbert C. Hoover Addresses Mining Engineers

Discusses Railroads, Shipping, Industrial Relations, and Other National Problems in which Engineers Are Directly Concerned

AS we go to press the American Institute of Mining and Metallurgical Engineers is holding its annual meeting, the feature of which has been the inaugural address of Herbert C. Hoover, delivered upon assuming the presidency of the Institute for the ensuing year.

In beginning his address Mr. Hoover spoke of the work which the engineers have done for the nation during the war and of the greater task now facing them.

"Even more than ever before," he said, "is there necessity for the continued interest of the engineer in this vast complex of problems that must be met by our government. We are faced with a new orientation of our country to world problems. We face a Europe still at war; still amid social revolutions; some of its people still slacking on production; millions starving; and the safety of its civilization is still hanging by a slender thread."

Mr. Hoover referred specifically to some of the great problems in this country in which engineers are interested. Brief quotations from these references are given below, as reported in the daily press. Speaking of the railroads and shipping, he said:

"The war nationalization of railways and likewise the war nationalization of shipping are our two greatest problems in government control awaiting demobilization. There are many fundamental objections to continuation of these experiments in socialism necessitated by the war. They lie chiefly in their destruction of initiative in our people and the dangers of political domination that can grow from governmental operation.

"Already we can show that no government under pressure of, ever present political or sectional interests can properly conduct the risks of extension and improvement, or can be free from local pressure to conduct unwarranted services in industrial enterprise.

"On the other hand, our people have long since recognized that we cannot turn monopoly over to unrestrained operation for profit nor that the human rights of employees can ever be dominated by dividends. The problem is easy to state. Its solution is almost overwhelming in complexity.

"As the result of war pressure we will spend over \$2,800,000,000 in the completion of a fleet of 1,900 ships of a total of 11,000,000 tons, nearly one-quarter of the world's cargo shipping. We are proud of this great expansion of our marine, and we wish to retain it under the American flag.

"Our shipping problem has one large point of departure from the railway problem, for there is no element of natural monopoly. Any one with a water-tight vehicle can enter upon the seas today, and our government is now engaged upon the conduct of a nationalized industry in competition with our own people and all the world besides. While in the railways government inefficiency could be passed on to the consumer, on the seas we will sooner or later find it translated to the national Treasury.

"Second, we may find it desirable to hold a considerable government fleet to build up trade routes in expansion of our trade, even at some loss in operation.

"Third, in order to create this fleet we have built up an enormous ship building industry. Fifty per cent of the capacity of our shipyards will more than provide any necessary construction for American account. Therefore, there is a need of obtaining foreign orders, or the reduction of capacity, or both.

"I believe, with most engineers, that with our skill in repetition manufacture, we can compete with any ship builders in the world and maintain our American wage standards; but this repetition manufacture implies a constant flow of orders.

## DEPARTMENT OF PUBLIC WORKS ESSENTIAL

"Our joint engineering committees have examined with a great deal of care into organization of and our expenditure on public works and technical services. They report that the annual expenditure on such works and services now amounts to over \$250,000,000 per annum, and that they are carried out today in nine different governmental departments. There is a great waste by lack of

national policy of coordination, in overlapping with different departments, in competition with each other in the purchase of supplies and materials and the support of many engineering staffs.

"They recommend the solution that almost every other civilized government has long since adopted—that is, the coordination of these measures into one department under which all such undertakings should be conducted and controlled.

## INDUSTRIAL RELATIONS A NATIONAL PROBLEM

"Another great national problem to which every engineer in the United States is giving earnest thought and with which he comes in daily contact, is that of the relationship of employer and employee in industry.

"We have until recently greatly neglected the human factor that is so large an element in our very productivity. The development of vast repetition in the process of industry has deadened the sense of craftsmanship and the great extension of industry has divorced the employer and his employees from the contact that carried responsibility for the human problem.

"I am daily impressed with the fact that there is but one way out, and that is to again reestablish through organized representation that personal cooperation between employer and employee in production that was a binding force when our industries were smaller of unit and of less specialization.

"Many of the questions of this industrial relationship involve large engineering problems, of which I know of no better example than that of the soft coal industry [a subject discussed by the A. I. M. & M. E. at their convention]. Broadly, here is an industry functioning badly from an engineering and, consequently, from an economic and human standpoint. Owing to the intermittency of production, seasonal and local, this industry has been equipped to a peak load of 25 or 30 per cent over the average load. It has been provided with a 25 or 30 per cent larger labor complement than it would require if continuous operation could be brought about.

"There lies in this intermittency not only a long train of human misery through intermittent employment, but the economic loss to the community of over a hundred thousand workers who could be applied to other production and the cost of coal could be decreased to the consumer. This intermittency lies at the root of the last strike in the attempt of the employees to secure an equal division among themselves of this partial employment at a wage that could meet their view of a living return on full employment.

## NATIONAL IDEALS SHOULD PREVAIL

"These are but few of the problems that confront us. But in the formulating of measures of solution we need a constant adherence to national ideals and our own social philosophy.

"In the discussion of these ideals and this social philosophy we hear much of radicalism and of reaction. In their present day practical aspects they represent, on one hand, roughly, various degrees of exponents of socialism, who would, directly or indirectly, undermine the principle of private property and personal initiative, and, on the other hand, those exponents who in various degrees desire to dominate the community for profit and privilege. They both represent attempts to introduce or preserve class privilege, either a moneyed or a bureaucratic aristocracy. We have, however, in American democracy an ideal and a social philosophy that sympathizes neither with radicalism nor reaction as they are manifested today.

"For generations the American people have been steadily developing a social philosophy as part of their own democracy—and in these ideals it differs from all other democracies. This philosophy has stood this period of test in the fire of common sense; it is, in substance, that there should be an equality of opportunity—an equal chance—to every citizen."

# The Engineer's Salary and Present Conditions

Compensation Should Be Based on the Value of the Dollar—How This Value Has Changed and Is Likely to Change—Underpaid Service a Menace to the Public

IN MECHANICAL ENGINEERING for February there was published (page 138) an abstract of the report of the Committee of Engineering Council on Classification and Compensation of Engineers. Herewith is published the main portions of an appendix to that report dealing with the important question of compensation from two different points of view: First, what increase should be made in engineers' pay to compensate for the great reduction in value of the dollar which has taken place in the last five years? Second, how may the intrinsic value of engineering service be determined?

## I. THE DECREASE IN VALUE OF THE DOLLAR

A great deal of misunderstanding and injustice would be avoided in all our industrial relations were there a clear understanding of the fact that all prices today, whether of wages or salaries, or commodities, must be compared with the change which has taken place in the value of the dollar before it can be determined whether the price, measured by an absolute standard, has moved up or down. It should be obvious to every one that the value of the dollar is measured solely by its purchasing power. Whether it be a dollar received as wages by workmen, a dollar received as salary by an engineer, or a dollar received by a manufacturer in payment for goods sold, the actual amount of value which will be received in each case *will depend upon the average amount of other commodities which the dollar received will purchase.*

### CHANGES IN WHOLESALE PRICES

The "Index Numbers" which are regularly published by various statistical bureaus are an average of the *wholesale* market prices of a large number of standard commodities. In making up the index numbers the prices of the different commodities and classes of commodities are weighted in proportion to the per capita consumption of each. Thus a comparison of the index number at a given date with the index numbers at preceding and following dates shows the change in average wholesale market prices and such a comparison shows also the change in the purchasing power, or value, of a dollar in the wholesale market.

TABLE 1 INDEX NUMBERS<sup>1</sup>

Date	Dun's Index Number	Corresponding number indicating relative power of one dollar

Dec. 1, 1919.....	244,639.....	400

<sup>1</sup> From figures compiled by R. G. Dun & Co. from market quotations of wholesale prices of 300 standard commodities, showing variations in the cost of living and in the purchasing power of the dollar. In making up the figures the commodities are arranged in seven groups, as follows: (1) breadstuffs; (2) meat; (3) dairy and garden; (4) other food; (5) clothing; (6) metals; (7) miscellaneous. The price of each of these commodities is multiplied by a figure determined as the estimated per capita consumption of that commodity. The commodities listed under "miscellaneous" include such articles as coal, petroleum, building material, and drugs, so that the individual's expense for fuel and shelter is at least partially represented in the total. These index numbers published by R. G. Dun & Co. are believed to be the most reliable record obtainable of price changes in the wholesale markets.

This is illustrated in Table 1, in which the numbers in the last column, representing the buying power of a dollar, are the reciprocals of the index numbers. The index numbers in Column 2, it will be understood, are the amount of money required to buy a certain amount of certain standard goods at wholesale on a given date. Thus if the index number on a given date is, for example, \$110, then on that date one dollar will buy 1/110 of this amount.

### CHANGES IN RETAIL PRICES

In order to determine the change which has taken place in the value of the dollar it is necessary also to investigate changes in retail prices as well as those in wholesale prices. Especially where wages and salaries are concerned, it is the changes in retail prices that determine the buying power of the dollar received.

In general, the changes in retail prices follow the general course of the changes in wholesale prices. There is, however, more or less variation in different localities. Where such variation occurs it will generally consist in a *greater* proportionate increase of retail than of wholesale prices. Under the stimulus of the abnormal demand of the past five years, which is chiefly responsible for the great increase in prices, it is common knowledge that the retailer has frequently advanced his prices faster than the wholesale dealer.

### CHANGES IN HOUSE RENTS

In the long run the prices paid for house rents and for personal service change to correspond with the change in commodity prices; but rents change more slowly than the market prices of commodities, so that allowance must be made for this "lag" in determining the change in value of the dollar. This is especially the case where such a sudden and rapid increase in market prices of commodities occurs as has taken place in the past five years.

Furthermore, the rise in rents varies in different cities. In some munition towns, rents rose with a bound in 1915, and so did prices for personal service. In most of the larger cities rents did not rise materially until 1919.

In order to determine accurately the change in value of the dollar in a given community, therefore, an estimate must be made of the change in retail prices compared with wholesale, and of the rate of change in rents and personal service charges.

The September Bulletin of the U. S. Department of Labor contains tables showing the results of the Department's investigation of the increase in the cost of living in 17 important industrial cities of the United States for December 1915, 1917, 1918, and June 1919 as compared with December 1914.

Averaging the figures for these 17 cities, it is found that the increase in the cost of living in June 1919 over December 1914 was 76.24 per cent. This so-called percentage of "increase in the cost of living" really represents the percentage of increase which has taken place in all prices, including rent and service, as well as commodities. Its reciprocal, therefore, represents the decrease in value of the dollar which has taken place.

### PRESENT PRICES COMPARED WITH 1914

In order to compare readily these Bureau of Labor figures with the Dun index numbers, Table 2 has been compiled, in which the prices of December 1914 are taken as a base and the percentage of increase is shown for each date to December 1, 1919.

As explained above, the chief reason why the "cost of living" figures have increased less rapidly than the increase in commodity prices is the delay in readjustment of house rentals. The

TABLE 2 PERCENTAGES OF INCREASE OVER DECEMBER 1, 1914 IN WHOLESALE PRICES AND IN COST OF LIVING AT VARIOUS DATES

Date	Dun's Index No for wholesale prices per cent of increase over Dec. 1, 1914	Bureau of Labor's per cent of Increase in Cost of Living Over Dec. 1, 1914; Average of 17 Industrial Cities.
Dec. 1, 1915.....	7.2.....	107.....
Dec. 1, 1916.....	35.4.....	149.4.....
Dec. 1, 1917.....	77.4.....	41.81.....
Dec. 1, 1918.....	85.6.....	73.40.....
June 1, 1919.....	88.3.....	76.24.....
July 1, 1919.....	83.7.....	.....
Aug. 1, 1919.....	94.7.....	.....
Sept. 1, 1919.....	92.0.....	.....
Oct. 1, 1919.....	90.1.....	.....
Nov. 1, 1919.....	92.2.....	.....
Dec. 1, 1919.....	97.1.....	.....

Bureau of Labor figures bring down the record only to June 1, 1919. Since that date there has been a great increase in house rentals all over the country. There are no statistics to show the amount of this increase and its effect on the cost of living, but there is good reason to believe that this increase, coupled with the general increase in charges for personal service that has taken place during 1919, and the advance of prices by retail merchants at a greater rate than the wholesale price increases, is sufficient to make the percentage of increase in the cost of living indicated by the Dun statistics a true record of the change in value of the dollar at the present time.

There is still another item to be considered. The percentage of increase in wholesale prices shown in Table 2 records the increase over the prices on December 1, 1914. A more accurate comparison would be to take the average prices for the entire year 1914 as the base with which to make the comparison. The average of Dun's index numbers for the 12 months of 1919 was \$122.20. The average wholesale prices of commodities on December 1, 1919, were therefore double the average prices for the year 1914. The value of the dollar today, therefore, in the wholesale market is just half what it was during 1914, and it is less than it was at any time during the war.

#### CHANGES IN "COST OF LIVING" AND IN "VALUE OF THE DOLLAR" ARE NOT THE SAME

The customary reference to the general increase of prices above reviewed as "the high cost of living" has tended to confuse the minds of many people. Some employers have argued that the high cost of living was not their affair. They have declared the real trouble to be "the cost of high living." On the other hand engineers or other professional workers, and many classes of salaried men, have hesitated to press claims for increased pay on the ground that changes in the cost of living make it difficult to live on their incomes. Such men rightly feel that their living expenses are their own private affair.

When, however, it is clearly understood that what has taken place is a change in the value of the dollar, the claim for an increase in the rate of pay measured in dollars rests on an entirely different ground. The proper and dignified position for the engineer is to assume that his work should receive at least the same compensation in absolute value that it received five years ago and that, therefore, the compensation measured in dollars should be increased by whatever amount is necessary to offset the decreased value of the dollar.

There can be no denial of the justice of this claim, even though the difficulty of satisfying it to the full extent in many departments of engineering work is recognized. The compensation of many engineers is dependent upon laws and ordinances, custom and precedent. Great inertia must often be overcome to effect a change. In many cases the compensation of the engineer, like that of many other public servants, is dependent upon revenue raised by taxation; and the difficulties in increasing tax rates to correspond to the great decrease in the value of the dollar are known to everyone.

Engineers engaged in business on their own account have to meet the difficulty of raising their fees to offset the changed value of the dollar, a task especially difficult in fields of engineer-

ing where work is inactive and the competition for it is keen; yet without such increase they cannot adequately raise the pay of their own employees. This illustrates anew the need for emphasizing the change in value of the dollar, rather than the change in living costs. The former is at once recognized to bear directly on fair prices for goods sold and for the fees charged by professional men as well as on wages and salaries.

#### HOW LONG WILL HIGH PRICES STAY ?

There has been reluctance to raise salaries to correspond to the changed value of the dollar because of the idea that prices were to drop back with the conclusion of the war. So far from this being the case, the above quoted records show that following the lull in business after the armistice prices have risen above even the war time scale and are now at the highest point ever reached. Business has largely readjusted itself to the changed conditions and the activity in some lines exceeds that registered during the war.

At the bottom of the changed price conditions is the surplus of demand over supply. The world urgently needs more food and coal and steel and cotton, more of the goods made from them and from other raw materials than are now being produced. The competition among buyers that sent prices soaring in the early years of the war is still an active force to maintain prices.

The only two things which can restore prices to their former level are increased production or decreased consumption. World wide disorganization of industry and of government, deficient capital and deficient transport facilities all tend to reduce production. The world of consumers, long held down to a war diet and war clothing, now eagerly seeks to replenish its larder and wardrobe and to repair and renew its stock of buildings and machinery.

The outlook is that it will take years to again organize the world's equipment for production and distribution, including finance, transportation by land and sea, and merchandising, so that the demands of consumers may be met as before the war and prices be brought back to former level.

The present price level is not considered merely temporary by such of our Government agencies as the Department of Labor and the Federal Reserve Board or by such economists as Irving Fisher and J. S. Holden. Substantial relief from the high cost of living, therefore, cannot reasonably be expected through a decrease in prices; it must be met by increases in salaries.

From such considerations as these, the Committee feels justified in urging that a readjustment of compensation should be based on the assumption that the present scale of prices is to continue for an indefinite time.

#### II. THE INTRINSIC VALUE OF ENGINEERING SERVICE

It will be generally agreed that the salary of an engineer ought to be at least sufficient to enable him to live in the manner which his position and responsibility call for, and in addition to repay within a reasonable time the investment in time and money he has made in gaining the education and experience which is necessary for his work.

Unfortunately there has been for fully a decade a tendency to lower the pay of engineers. The law of supply and demand has operated to reduce the pay of engineers in many branches of the profession far below the standards above defined.

By paying too low a rate for engineering service, the inevitable tendency has been to lower its quality. This has been especially marked in the case of engineers in Federal, State, and Municipal service. Here the inertia which prevails in all public affairs has prevented the engineers from receiving more than a trifling part of the increase in pay, measured in dollars, that is required to offset the shrinkage in the dollar value.

The obvious result has been to drive out of the public service the best and ablest men, who can obtain better positions elsewhere, and to leave only the men who by reason of age or inferior ability cannot make such a change.

# CHEAPENED ENGINEERING SERVICE MEANS WASTE AND DANGER

It cannot be too strongly emphasized that the public loses through cheap engineering service many times the amount it may seem to save through lower salaries. The professional engineer in a responsible position in designing, constructing, or executive direction of important work should have initiative, sound judgment, broad knowledge, and executive ability. Lack of these qualities often results in great loss of money, often by needlessly increasing the cost of work of which the public never knows.

This matter deserves emphasis here because where readjustment of salaries has taken place to compensate for the changed value of the dollar it has been common to confine the increase to the lower paid men and to do little or nothing for the men receiving salaries above \$2500 to \$3000. There is no longer an excuse for this, as the above review amply proves. The measure of seeming economy, also, is very small; because the engineers in the higher positions are few in number compared with the rank and file of professional workers.

## ROUTINE WORKERS IN THE PROFESSION

It is frankly recognized that there is another class of technical work of a routine order which calls for little in the way of initiative, originality, or judgment. Much of this routine technical work in the field, the office, the shop, or the laboratory can be and is being done by boys and young men with limited education and no more training than that afforded by a correspondence school or a few months study in a trade school. Most of this work does require, however, a degree of reliability and fidelity which deserves fair compensation. The best guide to fair rates of pay for this class of technical workers is found by comparison with the standard rates of wages paid to skilled workers in the trades. These workmen are now generally receiving rates of pay much higher than the routine technical

worker and in many cases higher than even the engineer who carries large responsibility for design or administration.

The Federal Government is now paying thousands of its highly trained clerical and technical force less than a living wage. Except for the temporary bonus of \$240 a year for positions paying salaries of \$2,500 or less, no attention has been paid to the constantly diminishing purchasing power of the salaries paid to this class of employees. On the other hand the Government has given full recognition to increased living costs in fixing the wages of organized labor.

A "shipfitter" in the Navy Yard, for example, receives \$1,750 a year while he is learning how to do his work. After three months of apprenticeship he gets \$2,000. If he is made a "straw boss" in charge of 12 or more men, he gets \$2,450, and if a "sub-foreman" in charge of 30 or more men, he gets \$2,900. A blacksmith (heavy fire) gets \$2,400. A "hammer and machine forger" (heavy) gets \$3,700.

In many instances the amount paid for skilled labor is greater than the amount paid to the trained Government engineer. Over 40 of the labor crafts were awarded a rate of wage of \$2,000 and more by the Labor Adjustment Board.

The skilled laborer is not required to know how to read or write, and he may receive full pay after an experience varying from two weeks to six months. The Government engineering employee, on the other hand, to get an equivalent amount of pay, must have had from two to eight years' experience, if he is not a technical graduate, and in many instances will not be admitted at all without a technical degree and then only with from two to four years' practical experience.

Even though a temporary oversupply of men trained in engineering work may make it possible to keep salaries for these brain workers below the wage of laborers, the inevitable result will be a dissatisfied working force, which carries out the daily routine without energy or good will, and the public's work will not be done with efficiency or economy.

# Civil Engineers Discuss Development Problems

## Features of Annual Meeting Are Discussions of Development Committee Report and Recommendations of Special Committee Appointed to Review It

THE Sixty-Seventh annual meeting of the American Society of Civil Engineers was held in New York on January 21 and 22. Chief interest centered upon the comprehensive report of the Committee on Development presented to the Board of Direction in October. The report of the Joint Conference Committee of the four Founder Societies was appended to the Development Committee's report and also came under consideration.

With regard to the technical activities of the Society the Development Committee recommended in part:

That local "sections" hold not less than four stated meetings per year and encourage joint meetings with kindred societies; that periodic joint meetings of the four national societies be encouraged; that the fortnightly meetings of the parent society be discontinued; that the semi-annual meetings of the parent society be supplemented by the addition of a spring and a fall meeting, held successively in different sections of the country in coöperation with local sections, and that at these meetings as well as at the Annual Meeting and the Annual Convention attention be given to technical and broad economic problems, and that at the Annual Convention at least half the time should be scheduled for the serious consideration of technical matters; that the present system of securing papers which depends wholly on voluntary offers and results in a limited variety of subjects be supplemented by papers that will fit into a definite logical program, directed by the Publication Committee and announced in advance for a whole season; and that papers describing works be brief on the narrative side, with more attention given to stating the technical lessons of successes and failures; that

so far as practicable the subjects of the papers should cover current progress, and development of the various important branches of civil engineering and simultaneous discussion of important papers by the local section should be encouraged; that the monthly *Proceedings* should be extended to include editorial work, abstracts and reviews of important engineering articles and subjects of popular interest to the great majority of engineers; that coöperation with the American Engineering Standards Committee be approved and that it be continued and extended but that the idea of developing this Committee into another association be deprecated; that the Board of Direction be requested to consider the advisability of compiling a book of recommended principles of practice and standards to follow the development of engineering; and that to carry out the intent of these recommendations effectively the technical editorial staff be under the direction of the Publication Committee.

A special committee of the Board of Direction appointed to study the report of the Development Committee and review its suggestions, offered the following criticisms of the Joint Conference Committee Report, which, as it has been stated, was included in the report of the Development Committee:

1 The Joint Conference Committee's report does not sufficiently confine the voting power of the proposed new National Organization to the corporate members of the present National Engineering Societies, and of such other allied technical societies as are clearly predominately professional in their aim, and who are equally careful with the present national societies in the admission to their membership.

2 The proposed new organization does not have close enough connection and coordination with the officers and boards of direction of

the present national societies and such other national and regional societies as it may see fit to admit to its membership.

3 The Committee's plan creates a large amount of new, somewhat complicated, and expensive machinery that appears to us to be unnecessary, and which it may be reasonable to doubt can be made to work smoothly for some time to come, at least insofar as the present experience of engineering societies has gone.

4 The plan for the new organization is so drawn as largely to deprive the present national societies of any considerable influence in large public or national technical problems in which they are naturally interested and in which they are presumably capable of having voice.

5 The plan commits the welfare of the engineering profession to a new and untied organization without history, precedent, or experience, from which semi-professional, and even semi-commercial local societies are apparently not only not barred, but possibly may become from time to time a predominating influence.

6 The representation in the new organization accorded to the four national societies is numerically insufficient in view of their numbers, experience and standing.

In view of these and other minor alleged objections, the special committee suggested that the officers and Boards of Direction of the present national and their affiliated engineering societies could form, ex-officio, a National Engineering Council for the purposes of professional unity, which would, in effect, continue the work of the present Engineering Council, and that to the council thus formed might be added, if desired, delegates from state and local councils to be formed throughout the country. [In this connection see also the account in this number of the Conference of the governing boards of the Founder Societies on January 23.]

## First Step Toward Federation of Engineering Societies

### A Conference to Be Called Immediately of National and Local Societies to Formulate Plans for a Comprehensive Organization

AN important all-day conference of the officers of the four national engineering societies—the first such meeting ever held—was called in New York on January 23 by Engineering Council to discuss matters relative to the Council and its public work and to consider the broad question of engineering organization as reported in the recommendations of the Joint Conference Committee of the Founder Societies. The Trustees of the United Engineering Society, the members of the Joint Conference Committee and of Engineering Council were also present, the whole gathering numbering ninety-five leading engineers from all sections of the country.

The feature of the meeting was the passage of a resolution as a recommendation to the several societies approving the recent report of the Joint Conference Committee and calling for a conference in the near future of representatives of engineering organizations throughout the country to formulate plans for a federation of engineering societies. This is probably the most important and significant step which has been taken toward securing concerted action by the engineers of the country in respect to their common interests and their participations in public affairs. The wording of the resolution was as follows:

WHEREAS, This conference of national engineering societies has considered the recommendations of the Joint Conference Committee of the four Founder Societies, therefore, be it

Resolved, That the conference adopts in principle that report and requests the Joint Conference Committee to call, without delay, a conference of representatives of national, local, state and regional engineering organizations to bring into existence the comprehensive organization proposed.

VOTED unanimously that if this conference be called together again, it be called for a meeting in Chicago on April 20.

The conference on January 23 was called to order by Vice-Chairman D. S. Jacobus in the absence of J. Parke Channing, Chairman of Engineering Council, who was ill. Dr. A. R. Ladoux, Vice-President, Am. Inst. Mtl. & Met. Engrs., was elected chairman of the Conference.

The Board of Direction then voted that the main question in the Development Committee's report be submitted to the society for action by letter ballot as soon as possible. The resolutions of the Board included a suggested form of the questionnaire to be sent to the membership. The wording of the questions was modified in subsequent discussion and was finally adopted as follows:

1 Shall the American Society of Civil Engineers adopt the principle of becoming an active national force in economic, industrial and civic affairs?

2 Shall the Society actively coöperate with other engineering and allied technical societies in promoting the welfare of the engineering profession?

3 Shall the Society coöperate in the formation of the comprehensive organization provided for in the Joint Conference Committee report?

4 Shall the recommendations of the committee regarding technical activities be approved?

5 Shall the Society be divided into sections to embrace all members?

6 Shall the directors in each geographical district be nominated and elected by vote of the corporate members resident therein?

7 Shall a portion of the Society dues be allotted to local sections?

8 Shall the present nominating committee be abolished and candidates for the offices of president, two vice-presidents, and treasurer be nominated by representatives of local sections in annual conference?

9 Shall the dues of all non-resident members above the grade of junior be increased to provide for greater activities of the Society, said increase not to exceed \$5 per annum?

A resolution was also passed authorizing the Board to add any questions that in its judgment were needful to develop the opinion of the members.

#### FUTURE OF ENGINEERING COUNCIL DISCUSSED

A paper prepared by Chairman Channing, read at the conference, reviewed the main facts regarding the present organization and work of Engineering Council, covering important activities which have been reported from month to month in the columns of MECHANICAL ENGINEERING.

The financial needs of Engineering Council were outlined by Charles T. Main, Past-President Am.Soc.M.E. He stated that \$45,000 was needed to continue the activities modestly for 1920, and \$25,000 to reimburse Chairman Channing for money advanced during 1919 to inaugurate and maintain the Washington office: total \$70,000. Total expended in 1919, \$49,600. Resources for 1920 now visible are: balance from 1919, \$900; appropriations by Member Societies, \$12,600; contributions in response to 50,000 appeals to engineers throughout the country, \$5,000; total \$19,000. Needed, approximately \$50,000. Whatever reorganization of, or substitution for Engineering Council may be made, the latter must continue as now constituted through 1920, and should be at the end of the year a well organized activity.

Resolutions were passed at the conference calling for the support of Engineering Council so that its present activities need not be curtailed. These were voted as recommendations to the several societies and asked for a contribution of \$5,000 for the year 1920 in place of \$3,000 as now provided; and further for \$1,000 from the Am. Soc. for Testing Materials instead of \$600. It was asked that appeals for contributions be made of \$2 per person in each of the societies for the support of welfare work during the interval before the recommendation of the Joint Conference Committee shall have been made effective.

#### REPORT OF JOINT CONFERENCE COMMITTEE

Following these matters there was a general discussion throughout the afternoon of the report of the Joint Conference Committee. This report, an abstract of which was published in Section 2 of MECHANICAL ENGINEERING for January, 1920, is in two

parts, dealing respectively with public activities of engineers and with activities of common interest to the four Founder Societies. The conference devoted its attention to the former, which presented tentative plans for "a single comprehensive organization to secure united action of the engineering and allied technical professions in matters of common interest to them." Certain specific objects which such an organization might have were pointed out in the report to be as follows:

- 1 To render the maximum of service to the nation through unity of action.
- 2 To give the engineers of the country a more potent voice in public affairs.
- 3 To secure greater recognition of the services of the engineer, and to provide for his advancement.
- 4 To promote *esprit de corps* among the members of the profession.

5 To provide the machinery for prompt and united action on matters affecting the profession, among which are:

- Registration of engineers;
- Washington office for engineering societies;
- Department of Public Works of the Government;
- Conservation of national resources;
- Publicity;
- Classification and compensation of engineers;
- General employment bureau;
- Engineering education;
- International affiliation of engineers;
- Industrial relations.

Commenting on these the Committee says:

"In the greater vision resulting from the world war it is apparent that no one alone can successfully solve the problems with which he is confronted. He needs the coöperation of his fellows. National problems demand united effort. The Joint Conference Committee believes that the greatest value of the proposed organization is in the united effort for the service of the nation, from which effort will result the greatest service to the individual."

#### NEW ORGANIZATION TO BE FROM BOTTOM UP

The tentative plan for the proposed organization called for the following component parts:

- 1 Local Affiliations, preferably under the auspices of local engineering societies or clubs, as follows:

- a "Local Associations" or "Sections" of the national engineering or technical societies;
- b Local engineering societies; and
- c Other local engineers and members of allied technical professions and associates.

These local affiliations when secured are to be headed up in:

- 2 A National Council, consisting of representatives of national engineering and technical societies and of representatives of local, state or regional affiliations or organizations.

State councils were also recommended wherever and whenever the local conditions warrant.

The proposed basis of representation on the National Council is for each local, state or regional affiliation or organization whose membership is not otherwise represented than through the national engineering or technical societies to have one representative to the National Council for a membership of from 100 to 1000 inclusive, and one additional representative for every additional 1000 members or major fraction thereof.

Each national engineering or technical society is to be entitled to one representative for a membership of from 200 to 2000 inclusive, and an additional representative for every additional 2000 members or major fraction thereof.

#### ENGINEERING COUNCIL MIGHT BE MERGED

In reference to the present Engineering Council, whose work has been so effective in the many matters of general concern among engineers, the Committee states:

"In preparing this plan the Committee has recognized that there exists in Engineering Council a tool which is engraving an

honorable record on the pages of professional history, but its limitations are well known and its poverty is chronic. If desired, Engineering Council can be moulded into this organization by making it more democratic and founding it on direct representation of all engineers, rather than appointment as at present.

The great object is to provide an effective body, widely and truly representative, modestly yet adequately financed, which will be neither autocratic nor aristocratic, which will at all times stand as the representative and defender of the profession in matters affecting its honor, welfare and common interest."

J. W. Alvord, Chairman of a committee appointed by the Board of Directors of the Am.Soc.C.E. to study the report of its Committee on Development and make recommendations with regard to it, presented the conclusions of this Committee, saying that the problem is first to consolidate the engineering profession within itself by knitting together the Founder Societies and other national societies equally broad in purpose and careful in membership; second, to affiliate semi-technical societies in such a way that they will not control. He said that the new organization proposed by the Joint Conference report is quite separate and distinct from the Founder Societies and that he would propose to depart from that Committee's plan by consolidating into the new National Council the directors and officers elected by the Founder Societies. To this and other similar proposals by various speakers objection was raised on the ground that an organization such as proposed by Mr. Alvord would not be democratic, builded from the bottom up, in a way to satisfy the urgent demands of the various organizations of engineers both large and small.

#### DISCUSSION ON JOINT CONFERENCE REPORT

At the conference the plans of the Joint Conference Committee, certain of which have been referred to above, were presented by J. V. W. Reynders, who said that:

"First, the movement should be democratic, and so far as possible membership of the Engineering Council should not be appointed on the new Council. Second, the plan should not be fathered by the Founder Societies more than necessary in order to avoid hurting the susceptibilities of those not affiliated with these societies. Any nation-wide movement will fail unless it is the outcome of a justifiable, as well as an enduring principle. There must first be an unmistakable and widely-felt sentiment. There must be plainly recognizable signs of powerful initiative. In the national societies are sufficient members to insure success of this movement. This is a constituency upon which we can build without fear of consequences."

Further discussion, in which a large number participated, hinged upon the form which the proposed organization should take; that is, whether it should be in some way related to the present Engineering Council through the reorganization of the latter or otherwise organized through the present governing boards of the national societies; or whether it should be based on initial action taken by membership of the leading societies both national and local as proposed by the Joint Conference Committee. The drift of the discussion can be summarized by brief reference to remarks by Dr. Jacobus, who said the great handicap on Engineering Council has been the feeling that it is organized from within. The moment we say we are going to reorganize Engineering Council it will spread a feeling abroad that Council is going to fix things to suit itself. It should come from without, not within.

Another question raised was the matter of representation on the National Council of the proposed organization, whereby the local representation is much larger than that of the national societies. To this R. L. Humphrey of the Joint Conference Committee replied that the members of the best local societies are so often members also of the national societies that the delegates from the local organization would usually be members of the national societies as well and that therefore the latter would be amply represented. He believed that it would add to the feeling of democracy if the men from the local affiliations had a larger proportion of representation on the National Council. It was specified in the report, however, that the local representation on the Executive Board would be more restricted.

# Government Activities in Engineering

*Notes Contributed by The National Service Committee of Engineering Council<sup>1</sup>*

## Congress Passes General Land Leasing Bill

After ten years of waiting, the General Land Leasing Bill has passed both houses of Congress, run the conference gauntlet and was finally accepted by the Senate on February 11th.

It is estimated that by the terms of the bill, the oil, gas, coal, phosphate, sodium, and oil-shale lands made available for leasing and development by private enterprises are approximately 75,000,000 acres of the public domain. This land is largely in the western states.

The conference report reserved the right of the Government to extract helium from all gas produced from such lands. A Senate provision was put back in the bill permitting individuals, or associations of individuals, to obtain limited licenses or permits to secure a supply of coal for strictly domestic needs.

The relief section of the bill relates to very valuable oil-producing lands, which are now involved in litigation. The purpose of the House language, which was finally retained, was to prevent the claimant or holder of excess acreage from disposing of such excess. This excess under the terms of the House bill would revert to the Government to be leased by competitive bidding. At the same time it does not prevent one, holding not more than the maximum amount allowed, from disposing of any part thereof. It also recognizes an exchange of interest in lands made prior to January 21, 1920, provided the exchange does not increase or reduce the acreage held in excess of the allowed maximum. Thus the status quo of the excess holder is not changed. It was thought best not to interfere with sales of oil lands which were made by claimants holding less than the maximum amount allowed. The Senate provision requiring substantial improvements to have been made prior to an oil-land withdrawal in Alaska was reinserted in the bill.

The Senate provision provided maximum charges by the Government of 20 cents per ton for coal, and 25 per cent of the value of oil produced. The House bill contained no restriction on these charges and the conference agreed to the House provisions. It was finally agreed that 70 per cent of the proceeds from past sales, bonuses, royalties, and rentals was to go to the reclamation fund and 20 per cent to the State. Of the proceeds from future receipts, 52½ per cent is to go to the reclamation fund and 37½ per cent is to go to the State. Ten per cent of both past and future funds is to be turned into the United States Treasury.

It will be recalled that this bill provides for leasing lands on the public domain in multiples of 40 acres, and the total allowed to any one claimant is not to exceed 2560 acres.

## Reclamation Service

The Reclamation Service has submitted supplemental estimates for \$5,000,000 to be expended during the fiscal year 1921. The Secretary of Interior's letter of transmittal pointed out the limitation on the Reclamation Service due to the money available in the Reclamation Fund. At the time the regular estimate was submitted it was anticipated that not more than \$7,873,000 would be available. When it became certain that the General Land Leasing Bill would become a law, it was possible to add at least \$5,000,000 more to the estimate, because the reclamation fund is to receive 70 per cent for past production and 52½ per cent for future production derived from the bonuses, royalties, and rentals provided in the General Land Leasing Bill. It is estimated that this will make between \$5,000,000 and \$7,000,000 additional available in the reclamation fund.

## Patent Legislation

Legislation covering the administration of patent law, the status of the Patent Office, and our international relations in patent work have been very active in Congress. The House has passed a bill ratifying a Patent Convention which will enable holders of patents in this country and South American countries to have their patents registered and cleared through a common office at Havana. The registration fee is very small—only a fraction of what it formerly cost to have these patents registered.

The Senate and House bills authorizing the Federal Trade Commission to accept and administer inventions, patents, and patent-rights have been reported to both Houses. This is for the purpose of benefiting and encouraging the public in an effort to stimulate inventions and to encourage their industrial use. This bill provides for cooperation as between individuals, Government, and other agencies, and with scientific agencies of the Government. The House patent bill providing for increase of force and salaries in the Patent Office has been rewritten and reported to the House calendar. It provides that the Commissioner of Patents shall receive \$6000 annually, the First Assistant to the Commissioner \$5500, and the Assistant Commissioner of Patents \$4500. Five examiners-in-chief are also provided with a salary of \$5000 each. Salaries of other officials are raised in proportion.

The bill proposing to establish a Court of Patent Appeals has been re-written by a sub-committee of the House Patents Committee and will be introduced to the House calendar shortly. A bill proposing to make a separate establishment of the Patent Office is now under consideration by another sub-committee.

## Tariff Legislation

Despite the fact that the Senate had threatened not to take up piece-meal tariff legislation, much of which had been passed by the House, some important tariff bills relating to magnesite, cobalt, chrome, zinc, tungsten, porcelain and scientific instruments have been ordered favorably reported by the Senate Finance sub-committee to the full committee. Some of these emergency tariff bills have been reported without change.

The magnesite bill provided one-half of a cent per pound on commercial ore; three-fourths of a cent per pound on calcined, deadburned and grain magnesite, and 10 per cent ad valorem and three-fourths of a cent per pound on magnesite brick. These are the same as the duties provided in the House bill. Laboratory, optical and scientific glassware also carry the same ad valorem duties as provided by the House, namely, 60 per cent on laboratory apparatus; 45 per cent on optical glass; and 45 per cent on scientific instruments.

The zinc bill was amended so that zinc-bearing ores of all kinds are to pay a duty of two cents per pound on the zinc content instead of one cent, as provided by the House bill. The bill was also amended to carry the cobalt duty of twenty-five cents. The tungsten bill was amended so as to provide for a duty of \$1.50 on the tungsten content of imports of alloy steel.

## Government Aid in Road Building

A new bill has been introduced by the Chairman of the House Military Affairs Committee which is intended to liberalize the conditions under which surplus motor vehicles may be transferred to the State Highway Departments. The bill provides for transfer of equipment other than motor vehicles, and is in accordance with the recommendations of the Bureau of Public Roads, which recently expressed its desire that the following materials be itemized in the bill, which in other respects is similar to the bill that has passed the Senate. The list of materials includes industrial railway equipment, conveyors, gravity, power, donkey engines, corrugated metal roofing, steel and iron pipes, etc.

<sup>1</sup>Engineering Council is an organization of national technical societies created to consider matters of common concern to engineers as well as those of public welfare in which the profession is interested. The headquarters of Engineering Council are located in the Engineering Societies Building, 29 West 39th Street, New York City. The Council also maintains a Washington office with M. O. Leighton, chairman of the National Service Committee in charge. This office is in the McLauchlin Building, 10th and G Streets, Washington, D. C. The officers of Engineering Council are: J. Park Channing, Chairman; Alfred D. Flinn, Secretary.

# Charles Warren Hunt Appointed Secretary Emeritus of the American Society of Civil Engineers

**A**FTER serving the American Society of Civil Engineers for twenty-eight years, three as Assistant Secretary and twenty-five as Secretary, Dr. Charles Warren Hunt, at this own request, has been relieved from active duty. Dr. Hunt will continue to serve in an advisory capacity. His relation will be that of Secretary Emeritus, this office having been created for him by the Board of Direction of the American Society of Civil Engineers by a resolution passed January 21, 1920. The text of the resolution follows:

WHEREAS, Dr. Charles Warren Hunt, after 25 years of devoted and efficient service as Secretary of the American Society of Civil Engineers, during which he has contributed to its upbuilding and prosperity to a degree which places the Society under lasting obligation to him, has indicated his desire to be relieved from active duty, and

WHEREAS, He possesses an intimate knowledge of the business of the Society and an extensive acquaintance with its membership which render his advice and assistance of the greatest value to the Society and its Board of Direction, the benefit of which they can ill afford to lose, therefore he it

Resolved, That Dr. Charles Warren Hunt be and hereby is appointed Secretary Emeritus of the American Society of Civil Engineers at a salary of \$9000 for the coming year, and a salary of \$6000 per annum thereafter with such duties as the Board of Direction may assign to him.

Throughout his administration, Dr. Hunt has kept closely in touch with the business details of the Society's office and its organization, and has conducted its affairs on sound business lines. The high professional standards of the Society have been maintained, and under his guidance and strong personality the Society has grown, not alone in numbers, but in professional prestige as well.

Dr. Hunt was born in New York City on May 19, 1858 and when only eighteen years old was graduated from New York University with the degrees of B. S. and C. E. This was in 1876, and for the next sixteen years he was engaged in the practice of his profession. His experiences were varied and included work on municipal parks, water works, railroads, and docks.

It was while associated with the Brooklyn elevated railway companies in 1882 that Dr. Hunt was elected Assistant Secretary of the society. This was a newly created office and while its acceptance meant financial loss he saw an opportunity to serve his fellow men and he did not hesitate to accept. From that time on the events in his career are intimately connected with the history of the American Society of Civil Engineers.

Bringing to the society the enthusiasm of youth, Dr. Hunt had well conceived ideas of the functions of a national engineering society. He believed it necessary for a technical society not only "to advance engineering knowledge and practice" but "to preserve the high character and professional qualifications of its membership; to maintain the dignity and standing of the organization; to keep in touch with and take proper action on all matters in which the relation of the Profession to the public is involved; and to do whatever is possible for its members individually and in general." This was Dr. Hunt's creed and to the realization of such ideals he devoted himself unstintingly.

Among the many developments which took place during Dr. Hunt's administration was the creation of Local Associations of the society. The formation of such associations had several times been considered, but it was not until 1905 that definite action was taken. In that year two associations were formed, one at Kansas City and the other at San Francisco. Their great success at once led to the formation of similar bodies in other cities, and at the present time the society has a total of twenty-five.

The house at 57th Street, which for over twenty years served as headquarters of the society, was also erected during Dr. Hunt's term of office. It was a building suited in every way to the needs of the society and only because of a desire to more thoroughly cooperate with the other national engineering societies it was vacated in 1916, when the American Society of Civil Engineers became one of the Founder Societies with headquarters in

the Engineering Societies Building, 29 W. 39th St., New York.

To Dr. Hunt the society is indebted for the cataloging of its Library. He early realized the importance of a library index and after two years of careful and concentrated effort completed the work which made the library of great use to the profession. Dr. Hunt was also a pioneer in the making of engineering "searches," a work which has now become so important in all engineering reference libraries.

CHARLES WARREN HUNT

During Dr. Hunt's term of office the publications of the Society have undergone several changes. In 1892, in addition to the regular *Transactions*, the *Bulletin* dealing with current events and containing short abstracts of the technical papers was begun. In January, 1896, the publishing of the monthly *Proceedings* was started, the technical matter contained in these being subsequently collated and published in volumes of *Transactions*. This method of handling society notes and technical papers was new in society publications, but it soon won universal approval and has been retained ever since. In 1899 the society began the publication in the *Proceedings* of a "list of current engineering articles of interest." This service, started in a modest way, was greatly appreciated by the membership and has been retained ever since as a monthly feature.

Dr. Hunt has always taken the greatest interest in matters pertaining to the profession at large. In 1903, when The American Society of Civil Engineers was invited by the Directors of the Louisiana Purchase Exposition to undertake the arrangements for an International Engineering Congress, he personally supervised and directed the work of organizing the congress, the securing, translating and publishing of papers, the reception and entertainment of foreign representatives, and the details of the many meetings.

Dr. Hunt has long served as a representative member on such bodies as the John Fritz Medal Board of Award, the Engineering Foundation, and the United Engineering Society. He has given freely of his time and energy for the advancement of the entire engineering profession, and his active participation in the affairs of the profession will be greatly missed.

# NEWS OF THE ENGINEERING SOCIETIES

American Society of Heating and Ventilating Engineers—The Engineering Institute of Canada—  
A. S. M. E. Akron Meeting—Engineering Society of Western Massachusetts

## Engineering Society of Western Massachusetts

A meeting of the Engineering Society of Western Massachusetts was held at Springfield on January 20, at the Springfield Gas Light Company's plant, State and Water Streets. A number of the members visited the plant in the afternoon. Following a dinner in the office building of the plant, an evening session was held at which Arthur S. Hall gave a description of the plant and Harold C. Andrew, an efficiency expert, spoke on Chemical Control of the Gas Industry.

## American Society of Heating and Ventilating Engineers

The twenty-sixth annual meeting of the American Society of Heating and Ventilating Engineers was held in New York on January 27, 28, and 29. The reports of the officers and council reflected the increased growth of the society during the past year. The society's Journal, beginning with the month of January, will be published monthly instead of quarterly. The Research Bureau of the society is now a functioning institution, as was evidenced by the data on heat losses from direct radiation presented by Director John R. Allen and given in part in the Engineering Research section in this issue.

The results of four years' experience in prevention of corrosion of pipe in the deactivating plant of a 12-story apartment building in New York City, were presented by F. N. Speller and W. H. Walker. The principle employed is to fill a storage tank with suitably prepared steel lathing designed so as to pack closely with an exposed surface of approximately 100 sq. ft. per cu. ft. of space. In passing the water heated to 160 deg. Fahr. through this metal, all the oxygen is fixed in the form of hydroxides which are readily removed by filtration through a sand filter. The result is water inactive toward iron or other metals, free from oxygen but otherwise unaltered in composition except for the presence of a small amount of free hydrogen resulting from solution of iron in the deactivating tank. The results have been entirely satisfactory. It is said the pipes carrying deactivated water have shown no measurable corrosion.

E. R. Knowles described various types of installations using pulverized fuel, and quoted figures indicating to what extent this form of fuel is being utilized. It appears that in the United States there have been used to date over 50,000,000 tons of coal in powdered form; there are about 6,000,000 tons of powdered coal now used annually in cement making; about 2,000,000 tons in copper roasting and smelting; about 2,000,000 tons in steel manufacture and about 200,000 tons for general power.

An Advance in Air Conditioning in School Buildings, by E. S. Hallett, carried the general note of progress into the field of school ventilation and presented a system of using ozone in a way apparently so reasonable and convenient that it undoubtedly points out an economical solution to the problem of improving health conditions in schools.

National consciousness was appealed to in two papers. The first, The Cooperative Movement, by James P. Warbasse, president of the Cooperative League of America, discussed this great world movement of cooperation, tracing its history through humble beginnings to the present prosperity which it now has in England, Belgium and other countries, and pointing out the steady progress it is making in the United States. The other paper, Work of the Construction Division of the War Department, by Major R. W. Alger, gave an account of the difficulties under which this division worked and the almost incredible things accomplished under such handicaps. It concluded with a plea for constructive planning rather than destructive criticism in

order that the country might be prepared should another great emergency overtake it.

Other papers were: Relations of Boiler Heating-Surface Area to Boiler Capacity, by P. J. Dougherty; Oil as a Fuel for Boilers and Furnaces, by H. H. Fleming; Oil Fuel, by F. W. Staley; Fuel-Oil Equipment, by John P. Leask; Oil Fuel versus Coal, by David Moffat Myers; Oil Fuel, by W. C. McTarnahan; and Color Schemes for Distinguishing Plant Piping, by H. L. Wilkinson.

## A Record Meeting of Canadian Engineers

The Annual and Professional Meeting of The Engineering Institute of Canada held in Montreal January 27, 28 and 29, was easily the most successful in the history of The Institute. In view of the fact that the percentage of members lost in the war was very appreciable, the attendance of over 450 was especially good. The unusual attractiveness of the social features is explained by the statement that this is the first year that ladies have been invited to attend and participate in the events of the week. The professional papers were both varied and important.

The program for the Annual Meeting, held on the first day of the convention, included, in addition to the business sessions, an address on Modern Highway Problems, the address of the retiring president, Colonel R. W. Leonard, and the inauguration of the incoming president, R. A. Ross. At a luncheon held for members and guests, greetings from The American Society of Mechanical Engineers were conveyed to the gathering by Calvin W. Rice, Secretary of the Society, who stressed the importance of all technical engineers becoming members of The Engineering Institute.

During the past year, The Institute has been cooperating with other engineering societies in an effort to secure for Canadian engineers a uniform registration law similar to that recently recommended by Engineering Council in this country. The monthly Journal of The Institute is now well established, provincial divisions including 18 branches are now actively working, and the membership has increased greatly in excess of previous years. During his recent visit to Canada the Prince of Wales accepted honorary membership in The Institute and Government official recognition of The Institute was accorded by the Minister of Labor in granting it representation at the Industrial Conference at Ottawa in September.

The Professional Meetings of the convention opened Wednesday, January 28, in one of the most important sessions, a discussion as to whether engineering training should be specialized or conducted in a general manner. Papers were presented by Profs. R. F. Ruttan and A. S. Eve, of McGill University. Dr. Ruttan spoke favorably of the plan adopted by the Massachusetts Institute of Technology whereby the student while still under the direction of the instructors leaves during the winter of his Junior year and for the period of from two to three months in each of four or five leading companies' works under actual conditions in the field, returning the following winter and completing his college course. The general feeling evidenced by the discussion was that the engineering graduate should be a man competent to "take up a thing and see it through."

Engineering activities in the province of Quebec were dealt with at the Thursday morning session of the convention. The water power resources, the public health administration and the highways of the province were the subjects discussed. In the afternoon three interesting papers were presented, The Policy of the Air Board of Canada, Pulp and Paper Industry and The Forests of Quebec.

Several important points touching upon the situation in the engineering world today were brought out in the address of the retiring president, Colonel Leonard. He emphasized the need for

the engineer's clear thinking, always working from cause to effect, to help settle the labor unrest of the present time and quoted from an address which W. R. Ingalls gave before the Canadian Mining Institute to the effect that the increase in production which has come about during the last century is not because men have grown any stronger but because mind has taught labor how to become more effective and has provided it with machines and organization. Further progress depends on the ability of the leaders of labor to instill the sound principles of an intelligent democracy into their followers so that they may have a sense of their duties and responsibilities to the public as well as their rights. He said, "If solutions are possible whereby the lot of the workman can be improved, the engineer—whose training and life work are devoted to the solution of practical problems—is the most capable of finding them."

Colonel Leonard urged coöperation among all classes and nations. He not only outlined various opportunities for Canadian engineers in Canada but implored them to turn to engineers of other nations for advice and thus increase their usefulness. This suggestion, as applied between the engineers of the United States and Canada, would be for the greatest good of the development of the engineering profession in both countries.

We congratulate The Engineering Institute of Canada on its wonderful prospects and are grateful for the words of an appreciation in its annual report for the address last year of our past-president Dr. Hollis, and for the benefit which it obtained from the coöperative arrangements with our Society with respect to the Engineering Index.

### A. S. M. E. Meeting at Akron

Cleveland members of the A.S.M.E. and members of the Cleveland and Akron Engineering Societies held an all-day convention in Akron on Tuesday, January 27, headquarters being established at the Firestone Club House, where the professional session was held.

A paper, illustrated with slides, was presented by John Schaub, superintendent of the Akron plant of the Wellman-Seaver-Morgan Company, on the subject Rubber-Working Machinery. The paper, while utilizing as examples the heavy type of machinery common to rubber-working plants, was more correctly a discussion of the application of quantity-production methods to the machining of parts usually considered large enough to be run singly through the shop as separate jobs.

In the Wellman-Seaver-Morgan plant mixing mills are carried through the machine shop in units of five for the larger castings, such as housings, mill boxes and driving gears, while the smaller parts are worked in lots of two, or three times that number. In the design of these parts such clearances are specified that practically all the patterns may be used for machine molding.

Before planing the mill housings for their final fit, they are run through a milling machine and the larger portion of the surplus cap stock taken off. Then, when the housings are set on the planer, in lots of ten, there remains but a finishing cut. Machine time is cut appreciably by using two set-ups and two different machines for roughing and finishing. Mill bearings are gang-planed in lots of twenty, after which the pad for the bearing cap is milled and the individual bearing set for the final boring.

Mill guides are first planed, then dropped into a drill jig for drilling, after which they are placed on a special angle fixture on the horizontal boring-mill table, the drilled holes being used as a register to hold the guides in position. A complete set of guides with the guide tees adjusted is bored at one setting. The boring bar is fitted with two tools, one for each mill-roll radius, so that when the guides which fit on the large roll have been bored the operator moves the table sufficiently to place the other pair of guides in line with the boring bar.

A bonus system for machine-time saving is in successful operation, and all saving on the estimated time is split with the workman on a fifty-fifty basis, who receives as additional compensation one half of the time saved, at his hourly rate.

Calenders are also built in lots of five and erected on a cast-

iron floor to insure correct alignment. A dummy roll, considerably lighter than the service roll, is used for scraping in the bearings to a perfect fit, eliminating much of the laborious work usually connected with roll fitting.

The calender is divided into units for assembling smaller parts, such as wind-ups, let-offs and roll-raising mechanisms, being put together by special assembly groups, after which the completed sectional units are brought to the erection floor for assembly.

A. O. Austin, of the Ohio Insulator Company, Barberton, Ohio, presented a series of slides illustrating the Ohio Insulator plant and gave a brief description of the purpose and operation of each machine shown.

Following a luncheon at the Firestone club house the convention divided into three main inspection groups. One section of about thirty members visited the plant of the Ohio Insulator Company, under the guidance of Mr. Austin, and had an opportunity to view the manufacture of large porcelain insulators, ranging in height from two inches to almost five feet. A demonstration of high-tension insulator testing was given, a voltage of 330,000 volts and a frequency of 35,000 being used. This voltage produced a standing spark 36 in. or more in length. During the test a novel feature was introduced by subjecting the insulators under test to all the conditions met in a severe rainstorm.

The group electing to inspect the Wellman-Seaver-Morgan plant was taken first to what is known as the "Old Plant" building and there shown two 52,000-hp. hydraulic turbines under construction, both for use at Niagara Falls. The magnitude of these turbines is shown by the fact that the cast-steel spiral casings have a water intake 7 ft. 6 in. in diameter. Other machinery under construction included rubber-mixing mills, calenders, washers, steam tire-vulcanizing presses, condensers for marine engines still being built for the U. S. Merchant Marine, and also the first lot of "Akron" tractors to be sent through the plant.

Passing through the galvanizing room, containing a tank capable of holding 100 tons of metal, and one of the largest in the country, the party completed its tour by inspecting assembly methods used in constructing mechanically stirred gas producers.

For the rubber-working industry the Goodyear Tire and Rubber Company acted as host, groups of eight men and a guide being sent through the plant, following, as closely as possible, the flow of the rubber through the plant from the raw material warehouse to the finished product. The manufacture of two types of inner tubes was shown, of lapped tubes—formed from sheet rubber much as lap-welded pipe is formed from skelp—and of laminated tubes, these latter being made up from a thin sheet of prepared rubber which is rolled around a mandrel of the proper size until it is covered by two or more complete layers. Both types were steam-vulcanized.

Guides for the inspection groups were taken from the organization in the Goodyear plant known as the "Flying Squadron," made up of high-school and college graduates, working out a kind of engineering apprenticeship with a view to being located eventually in the department most attractive to them individually.

The evening dinner was served at the Goodyear plant, with Dean Ayer, president of the Akron Engineering Society, as toastmaster. Dr. D. C. Tremaine, from the National Industrial Speakers' Bureau, discussed the topic, Human Nature in Industry. Introducing the factor of the human element in industry, the speaker brought out its present status, as compared to that of business, and emphasized the need for easy access to the manager's office by the worker. The responsibility for present-day business is not one-sided, but rests equally with worker and management. The growing importance of each man to the organization and to the industrial life of America was shown in its bearing on the relation of increased production to the high cost of living.

While the day's program was styled a "convention," there was nothing in the papers presented, the talks, inspection trips or the evening dinner to render it in the least bit formal. Primarily, the day was planned to afford an opportunity for engineers of Cleveland to meet engineers of Akron, and for them to enjoy together a glimpse into some of the industries which are typical of the manufacturing progress of the Rubber City.

## Western Society of Engineers Holds Annual Meeting and Discusses Projects for an Engineering Building and Affiliation of Sections with the National Societies

The fiftieth annual meeting and dinner of the Western Society of Engineers was held in the Hotel Morrison, Chicago, January 28. Four hundred members of the Society were in attendance.

Major General Leonard Wood, U. S. A., the principal speaker of the evening, declared that the establishment of a National Department of Public Works would be of great benefit to this country. He said the Engineer's Reserve Corps should be maintained at maximum strength, for it had proved its ability in the great war, both at home and abroad.

Engineers should take an active part in public affairs, he asserted. All colonial development of the United States has been dependent on the work of the engineer, but after their labors in establishing lines of communication and transportation improving sanitary conditions and establishing a basis for commercial activity, they have been content to let the remainder of the work be taken over entirely by the administrative forces of the country.

A. Stuart Baldwin, retiring president, gave a masterful address bringing out the need for more cooperative action among the members of the Society.

There must be a more stern and conscientious application of the "Golden Rule," if civilization is to stave off a period of decadence in the future, he said. The engineer must analyze the forces that today are a menace to the peace and prosperity of the world and are directly antagonistic to "Do unto others as ye would have them do unto you."

In beginning his address, Mr. Baldwin said that a development committee had been appointed to study the status of engineers in Chicago and vicinity, and thereafter enter upon a campaign for bringing together the engineers from all branches of the profession, organizing them into one great society and so coordinating their activities as not only to gain professional prestige but to function as a strong and useful member of the body politic. The Society could look forward at no distant date to doubling its present membership.

The next important move should be the construction of an adequate building in Chicago as an engineering center. "With so large a membership," he said, "the work of the directors and executives must to a much greater extent be de-centralized and thrown upon the heads of the Sections, each of which must become to a certain extent a self-contained engineering society, in its own specialty, all cooperating for the common good. If each Section were the working local branch and representative of the national society with which the most of its members were affiliated and if the national societies would father these sections and become their working associates, the Sections would become tremendously strengthened and not only serve to strengthen the Western Society of Engineers, but act as a reservoir from which the national societies would gain strength and inspiration. The national societies all have need for local work on the part of their members. The opportunities for getting together nationally occur but a few times during the year, whereas local sections should be able to meet monthly or even more frequently, if necessary. It will undoubtedly be found that those members of a national society who are able to get together locally most frequently for papers, discussions and consideration of society matters, will be the most influential in the affairs of the national society."

Frederick K. Copeland, Mem. Am. Soc. M. E., the new president, laid down the ambitions of the society for the coming year. Briefly, they are: (1) Increase membership; (2) Organize more sections to aid in professional development of engineer; (3) Pay an important and decisive part in civic affairs; (4) Develop the social activities of the engineer beyond the confines of engineering alone.

"Each and every one of us must show our loyalty and willingness, by giving of our time and our energies, to take part in this great development of the Western Society of Engineers," he concluded.

Mr. Copeland is president of the Sullivan Machinery Co. and for a number of years has been active in the affairs of the Western Society. He was admitted to membership in 1892. In 1919 he was appointed first vice-president to fill the unexpired term of Kempster B. Miller. Besides being active in the affairs of Engineering Council, Mr. Copeland is a director of the National Department of Public Works Association. He is president of the General Committee of Technical Societies of Chicago.

The rapid growth of the Western Society of Engineers has made it necessary that additional facilities as well as space for the administrative force of the organization be obtained. Two additional rooms adjacent to the present quarters of the society on the 17th floor of the Monadnock Building have been obtained and will be available May 1st. The tentative plan is to devote the present quarters to the library, reading rooms, auditorium and committee rooms. The records of the society will be moved to the new quarters as far as will be practicable. Such a move as this will add materially to the advantages to be obtained from the library in that more shelving space will be available, it will be possible to add to the comforts of the reading room and committees may work in rooms in direct contact with the reference files of the society.

H. T. ELLISTON.

## SELF-SUPPORTING CHIMNEYS TO WITHSTAND EARTHQUAKES

(Continued from page 160)

reinforced-concrete chimney is that given in Turneaur and Maurer's Principles of Reinforced-Concrete Construction, except that the temperature reinforcement was increased materially beyond that indicated in this textbook. The allowed tensile stresses of the reinforcing steel, as well as the compressive stresses in the concrete, due to earthquake, were normal. The temperature stresses alone were slightly above normal for concrete, and less than normal for steel. When these were added to the earthquake stresses, the final result gave a stress safely within the elastic limit for steel, but considerably above what would be considered a safe allowance for the compressive stress of concrete. Investigation of the temperature stresses shows that the above condition is unavoidable, and the conclusion is that while a chimney so designed would not fail by falling during an earthquake, it is easily believable that the combination of earthquake and temperature stresses would result in serious fractures at critical portions of the chimney.

A very important point in the design of such chimneys is the assumption of the difference between the temperature of the gases within the chimney and the temperature of the outer shell of the chimney. Some tests made by the writer indicated that this temperature difference is greater than was assumed in the example given by Turneaur and Maurer, and further data along these lines would be of much interest to designers.

The writer was unable to find any new material of light weight and of low conductivity to be used in lieu of the ordinary concrete or brick lining of a reinforced-concrete chimney; for manifestly it is highly important to minimize the mass of the chimney subject to vibration. It was finally necessary to assume a brick lining. The question then arose as to the height to which this should be carried to minimize temperature stresses in the unlined upper portion of the chimney, which, from experience with earthquakes, is the weakest section of the chimney. It was considered impracticable to carry the chimney lining to this critical section; which indicates a manifest defect of the reinforced-concrete chimney for withstanding earthquakes.

It has recently been suggested to the writer by Mr. C. A. G. Weymouth that in the building of reinforced-concrete chimneys to withstand earthquakes it would be advantageous to use terracotta concrete, as developed by the Concrete Ship Section of the Emergency Fleet Corporation. As is well known, terracotta concrete materially reduces the weight per cubic foot, and in addition has a high compressive strength. It should be pointed out, however, that any saving in the weight of the chimney shaft, as compared with the ordinary concrete construction, would, of

necessity, be made up by an increase in the weight of the base of the chimney to give the necessary stability against overturning from wind pressure.

The requirement under [7] for the deflection of the chimney shaft should be made with some margin of safety. No data are at present available, but it should be borne in mind that any increased elasticity of the chimney should not be secured at the sacrifice of strength actually necessary to resist moments in the lower portion of the chimney shaft.

It is hardly necessary to state that the chimney designer must give due consideration to the shear produced by earthquake, as well as the shear due to wind pressure; other stresses, however, are usually the determining factors.

It is of course obvious that a chimney to withstand earthquakes should be constructed of materials of maximum strength, of minimum weight, and with maximum elasticity. So far, this combination seems to be best supplied in the use of self-supporting steel chimneys, regardless of whether the conditions of operation require a chimney lining. In California, at least, the earthquake evidence testifies eloquently in favor of the use of steel chimneys.

In closing, the writer will state that while the ultimate solution of the earthquake chimney problem appears impossible in an accurate sense, it is nevertheless to be hoped that some of our engineering physicists will give further study to the rather special questions which it involves.

## FIRST TRANSCONTINENTAL MOTOR CONVOY

(Continued from page 150)

This was in running through Iowa where the roads were very good. A very different class of troubles developed when running through the western section of the trip as indicated, for example, by what happened during such an average day as August 13.

Departed Rawlins 6:15 a. m. 22 mi. west detour was made around dangerous bridge over dry creek bed. At Creston Station a Class B water tanker No. 89216 ran off road on abandoned railroad grade and rolled over 270° resting on left side. It was righted by 2 Class B's and proceeded under its own power in 20 min. No serious damage. Class B tank trucks appear to be somewhat top-heavy, and driver claimed that this truck was very hard to steer and almost impossible to keep on road. Trailmobile kitchen broke spring and bent axle. At Wamsutter, F. W. D. No. 415767 stopped to tighten up front universal joint and it was also found to have a broken radiator support stud. Two G. M. C.'s, Garford, Class B and Dodge had carburetor trouble. 3 mi. east of Tipton Station, Class B Machine Shop No. 41199 ran off road into soft sand hole and had to be towed out by Militor. Right wheels of Mack Blacksmith Shop No. 4 sheared through 16-3" x 10" bridge floor planks, and narrowly averted dropping into 12' ravine. Bridge reinforced and truck rescued in 55 minutes. Six other bridges reinforced by Engineers and it seems that timber in this dry atmosphere loses its elasticity and becomes very brittle. Camped on Red Desert, on barren sandy plain. No inhabitants or buildings other than railroad personnel and property. Nearest natural water supply 16 miles. Fair and warm. Fair dirt roads. Made 58 miles in 10½ hr. Arrived Tipton Station, Wyo. 5 p. m.

Even that, however, cannot be called the worst and to judge of the troubles that the Convoy had to handle it may be well to look, for example, the log for August 30 to September 1.

Departed Fallon, 6:30 a. m. Followed direct road to Carson City, via the Lahontan Dam. Heavy trucks had some difficulty in getting through soft sand holes about 2 miles out of camp. Five or more trucks were chained together and men not driving helped by pushing. Delay ½ hr. White Reconnaissance Car No. 111505 had to replace spark plug on account of broken porcelain. Required 11 hrs. to move Convoy from Fallon to a point 12 mi. west, on account of several stretches of unstable, dry sand up to 1½ ft. deep, and wet quicksand. All heavy vehicles, including Cadillacs had to be pulled and pushed through by combined efforts of tractor and men, over wheel paths made of sage brush. Two Class B tankers sank to a depth of 5 ft. In sand, requiring extensive excavation and construction of false work of railroad ties to aid tractor in rescue. Dodge Light Delivery No. 20901 broke generator drive chain, damaging oil pump drive. One small bridge broke down. Convoy met by Gov. Boyle, etc.

Chicken dinner. Co. E arrived 11 p. m. Fair and warm. Poor gravel roads. Made 66 miles in 20 hrs. Arrived Carson City, Nevada, 2:30 a. m. (31st).

Aug. 31. Carson City, Sunday rest period. Tractor towing Mack with bad clutch, arrived 11:30 a.m. after resting on road until daylight. Inspected and adjusted equipment. Changed several tires, pressing done at Reno. Transportation provided and personnel taken to Hot Springs for bathing. Union religious services held at camp on Capitol grounds, at which Governor Boyle made address of welcome. At officers' meeting instructions were given relative to operation precautions to be taken on King's Grade climb tomorrow. Fair and warm.

Sept. 1. Departed Carson City 6:30 a.m. Convoy arranged with heaviest vehicles in lead. Temporary control established at base of King's Grade for inspection of steering gears, brakes, tow chains and wheel blocks, also for spacing vehicles 100 yds. apart. Full supply of gasoline, oil and water verified. Experienced drivers only allowed to drive and one man on each vehicle stood ready to block the wheels at each halt. All passengers required to be on the alert for any emergency. Nevada State Highway Dept. suspended all eastbound traffic from 6:30 a.m. until after Convoy had crossed the Sierras. Motorcycle riders required to maintain vehicle spacing and inspect bearings every 4 miles. Reached altitude of 7630 ft. at summit over narrow, winding road of sand and broken stone, cut out, and in places built up on, mountain side. Total climb 14 mi. made in 6 hr., slow progress being necessary to prevent accident. Grades 8 to 14 per cent. Crossing Sierras without accident may be considered noteworthy achievement for heavy vehicles. Class B broke fan belt. One Trailmobile kitchen overturned and was wrecked, and was shipped to San Francisco. Mack broke connecting rod, pushing piston through top of the cylinder and cracking crank case, near Glenbrook, where noon "chow" was served, and was left there to make emergency repair by cutting out damaged cylinder, piston being welded and cemented in place. At California-Nevada line the War Camp Community Service and Mayor's Comm. of San Francisco gave fine barbecue and enthusiastic welcome. Mr. Celio, owner of Meyer's Ranch, served refreshments in evening around huge camp fire, while the Firestone representatives furnished movies and snacks. Scenery throughout day of greatest beauty, especially at Lake Tahoe. Fair and cool. Fair gravel roads. Made 34 miles in 13½ hrs. Arrived Meyers, Cal., 8 p.m.

On the whole it may be well to repeat what has been said before as to the results, namely, that the pioneer undertaking of its kind, the First Transcontinental Convoy, was a successful operation and the experience gained during this trip will prove invaluable not only to the Army but to all users of motor trucks in general.

## ELECTRIC POWER SUPPLY OF SOUTHERN TEXTILE MILLS

(Continued from page 161)

Early practice employed large group motors, but comparatively little benefit was derived from their use. The practice now is to use small motors ranging in size from 0.5 hp. on looms to 5 and 7.5 hp. on spinning frames directly applied to the machines. The resulting benefits, principally in production, are a great deal more than sufficient to offset the extra cost for this type of installation. A great many of the old mills, either with mechanical or with large group motor drives, are changing to these individual motor drives. In some departments where it is still customary to use group motors, a number of small units are used, instead of a few large ones. The illustration on page 161 being typical.

Some of the mills so equipped have been in operation for four or five years, and the results justify the expectancy of an increased production, averaging probably 8 per cent, together with a very low maintenance cost. Incidental to the main advantage of increased production, are such minor but well worth while advantages as greater cleanliness, better lighting conditions, and flexibility of operation.

A very strong argument for purchased power is the flexibility it provides for the growth of industrial plants. A plant can be built requiring only a very small amount of power, with the feeling that unlimited extensions can be carried out without fear of power limitation.

The treatment accorded by the power companies to their customers has in general been quite liberal, and the rates have not been increased in line with the increased cost of other commodities.

The illustrations show typical examples of generating plants, distribution lines, substations, and motor installations.

# LIBRARY NOTES AND BOOK REVIEWS

**APPLIED CALCULUS.** Principles and applications. Essentials for Students and Engineers. By Robert Gibbs Thomas. D. Van Nostrand Company, New York. 1919. Cloth, 5 x 7 in., 490 pp., 45 exercises, 196 illus., \$3.

In this college text-book, the author has aimed to make clear the basic principles of calculus and to show that fundamental ideas are involved in familiar problems. Effort has been directed toward the attainment of a working and fruitful knowledge of the elements of the subject and an ability to use it efficiently.

**ATLAS AMERICA LATINA.** General Drafting Company, Inc., New York. 1919. Cloth, 11 x 16 in., 196 pp., \$20.

The detailed maps which form the most important part of this atlas have been prepared from the best authorities. They cover Mexico, Central and South America and the West Indies and are drawn to a uniform scale of fifty miles to the inch. Towns, railways, administrative divisions and physical features are clearly shown and a geographic index is provided.

The atlas also contains maps showing steamship routes, ocean currents, natural vegetation, prevailing winds, summer and winter rainfall and temperatures, principal products, principal minerals and the language divisions of Latin America, as well as charts showing the foreign trade of each country and descriptive articles concerning their possibilities and conditions.

**AVIATION.** Theoretical-Practical Text-book for Students. By Benjamin M. Carmina. The Macmillan Co., New York. 1919. Cloth, 8 x 5 in., 172 pp., 92 diagrams, table, \$2.

The author discusses the theory of flight and the construction, rigging and maintenance of airplanes, and gives suggestions on flying. The treatment is non-mathematical throughout, but an appendix is included which gives the mathematical analysis of the laws governing flight.

**DER BAU DES DIESELMOOTORS.** By Kamillo Korner. Julius Springer, Berlin. 1918. Cloth, 11 x 7 in., 350 pp., 500 diagrams, 30 marks.

The present work is devoted to the practical details of Diesel engine construction and omits all discussion of theoretical considerations. The various elements of engines are discussed in detail and examples of the usual designs are given.

**CHILTON TRACTOR INDEX.** Vol. 3, No. 1. Chilton Company, Philadelphia. 1920. Paper, 10 x 7 in., 478 pp., \$1.

The Tractor Index is a directory of the farm tractor industry of the country, which gives in tabulated form the specifications of the tractors on the market, lists of tractor and power farm machinery manufacturers, makers of parts and accessories and farm trucks. In addition to these directories, the volume includes a collection of data and articles on power farming, farm lighting plants, tractor testing, tractor standards and other topics of interest to users and dealers.

**CONTROLLERS FOR ELECTRIC MOTORS.** A Treatise on the Modern Industrial Controller, together with Typical Applications to the Industries. By Henry Duval James. D. Van Nostrand Company, New York. 1919. Cloth, 8½ x 5 in., 397 pp., 259 illus., \$3.

The aim of this volume, which is based on a series of articles published in the *Electric Journal* during 1917 and 1918, is to provide students, operating engineers and users of electrical apparatus with a good general account of their principles of operation.

**THE ELEMENTS OF ASTRONOMY FOR SURVEYORS.** By R. W. Chapman. J. B. Lippincott Company, Philadelphia. 1919. Cloth, 5 x 7 in., 247 pp., 56 diagrams, \$1.75.

Although there are several excellent books on surveying that deal more or less thoroughly with astronomical observations, the

author of this work believes that there is a need for an elementary work suitable for the student and for the surveyor who is taking up astronomical observation for the first time. The present work is an attempt to provide an elementary exposition, not only of the practical methods of observation and computation, but also of the main principles that must be thoroughly understood if the surveyor is to be master of his profession.

**GOVERNORS AND THE GOVERNING OF PRIME MOVERS.** By W. Trinks. D. Van Nostrand Co., New York. 1919. Cloth, 8 x 9 in., 264 pp., 140 illus., \$3.50.

This volume aims to present the principles and essentials of the subject in such a manner that the reader may be able to judge existing and future types of governors as well as the properties of prime movers with regard to regulation. It has been written to provide a text-book on the general subject of governors and governing, upon which, the author states, there is no book of any consequence in English. A selected bibliography is included.

**THE GREAT LAKES RED BOOK.** A list of over 1,000 Vessels of the Great Lakes, with the Name of Owner, Captain and Engineer of each Vessel. The Marine Review, Cleveland. 1919. Paper, 5 x 3 in., 139 pp., \$1.

Gives a list of the fleets upon the Great Lakes, as well as owners, captains and engineers. There is also a table showing capacity of ore-carriers and a port directory.

**MINING MATHEMATICS SIMPLIFIED.** By James Wardlaw, Sr., Scottsdale, Pa. Cloth, 7 x 5 in., 189 pp., \$2.50.

This volume gives simple arithmetical solutions for the problems which confront the practical miner. The author is engaged in preparing miners for examinations for certificates as fire bosses, foremen, etc., in the Pennsylvania bituminous coal-field and has written this text for their use.

**THE NEW AMERICAN THRIFT.** The Annals of the American Academy of Political and Social Science. Vol. 87, No. 176, Philadelphia. 1920. Paper, 248 pp., \$1.

Contents: Introduction; Thrift for the Individual and the Family; Thrift for the Nation; American Needs for Capital, Typical Examples; Thrift in Resources and Industry, Typical Examples; The Investment of Savings; The Promotion and Practice of Thrift in Different Countries; Suggestions for Promoting Thrift.

A symposium by a number of bankers, economists and business men on the desirability of thrift in national and individual life. The problem is broadly presented and discussed in its various phases by experts.

**A TEXTBOOK OF RAND METALLURGICAL PRACTICE.** Vol. 2. By Ralph Stokes, Jas. E. Thomas, G. O. Smart, W. R. Dowling, H. A. White, E. H. Johnson, W. A. Caldecott, A. McA. Johnston and C. O. Schmitt. Second edition, revised. Charles Griffin & Company, Ltd., London. 1919. Cloth, 9 x 6 in., 462 pp., 467 illus., 25 shillings.

This work was prepared in 1911 by a body of technical men actively engaged in current metallurgical practice upon the Witwatersrand, to provide a textbook giving a detailed account of the methods in actual use in that district, both mechanical and chemical.

The present volume, which discusses the design and construction of reduction plants and the transport of materials is by C. O. Schmitt. No radical change in practice, has occurred since the publication of the previous edition, but considerable progress in the development of the use of heavy stamps, and tube mills, and a corresponding advance in the methods of classification and amalgamation have been made. This revised edition has been prepared in the light of these improvements.

## Reliability of Materials and Mechanism of Fractures

Behavior of Materials Under Test and in Actual Use Discussed by Distinguished French Engineer

By CHARLES DE FREMINVILLE<sup>1</sup>, PARIS, FRANCE

*It is a common experience that the behavior of materials in practice does not always agree with their behavior under test; designs worked out from data secured from test pieces have not always proved satisfactory, and actual machines have had to be modified from the experience of practice. The differences between test predictions and actual results are set forth in the following paper, and it is shown that the reasons for the discrepancy between test and actual conditions can be determined by an analysis of the mechanism of fractures of the test pieces and of actual specimens. Such an analysis reveals the fact that the mechanism of the fracture follows certain laws which can be formulated. The paper also deals with methods of designing members so that stresses in them do not conflict with the laws of mechanism of fracture. Pieces can be so designed and so assembled that the stresses in them largely avoid the conditions of fracture, and it is significant that when such design and assembling is carried out, the behavior of the actual machines is much more similar to the behavior of the test pieces themselves.*

WHEN the author was invited to read a technical paper before The American Society of Mechanical Engineers the first subject which came to his mind was, The Reliability of Materials, chiefly because of his previous experience in the use of metals and with the testing of metals. If that word "reliable" impressed itself upon his mind, it was certainly because it is a word of which he has realized the full meaning in America, where the people are always looking for something reliable: reliable information, reliable products, reliable men; a country in which he found so many reliable friends, and which has proved herself so prominently and so thoroughly reliable in her immense effort to save the mutual ideal of civilization of France and America, which cannot conceive Science associated with an ideal other than Liberty.

Reliability is the quality we desire in the metals we use, but it is very difficult to ascertain it through a short test. The reliability of materials is like the reliability of friends. Whatever brilliant qualities they may exhibit, their reliability is known only in the long run, so that in the case of an apparent failure, the qualities of a metal, like those of a friend, should not be questioned too quickly. It is not enough to know the intrinsic qualities of the metal; a very careful study of the circumstances under which the failure occurred must also be made, and it is this fact which has made the study of fractures and of the mechanism of fractures one of great interest to the author.

During the early days of the automobile industry the problem of resistance of materials began to be considered in a new light. The first motor cars that were built were designed with factors of safety then generally accepted for the resistance of medium-

carbon steel. But the engineer soon came into contact with the sportsman and was tempted to put into the gearing a stress much greater than the one for which it had been made. One of the problems to be solved, therefore, was to secure a material which could safely be used for gears.

At that time steel makers' had produced, among certain other new products, ternary steels, which showed brilliant promises of new qualities if the results of the laboratory tests to which they had been submitted could be taken as a proof of their reliability.

Viewing the question of material for motor cars in a general manner, the constituent parts appeared to belong to two distinct classes. The first included such parts as gears, crankshafts, connecting rods, etc., which had to withstand severe normal shocks. Also only a small amount of wear was allowable and the class of accidents to which they were liable was limited, being chiefly those of seizing or an encounter with stray nuts or bolts.

The parts of the second class did not have much stress imposed upon them in ordinary service, but they did have to meet with what can be termed "normal accidents," and were therefore expected to bend to a certain extent without ceasing to fulfill their duty. To this class belonged front axes and, more generally, all the parts connected with the steering mechanism. For these, the "normal accident" can happen very frequently. It is almost impossible to say that the wheel of a car will not come rather abruptly into contact with a curbstone, or even with the wheel of another car. In such case something must yield or break. It is of course but natural to hope that something will yield and that this yielding has been foreseen; also that it will take place on a piece easily seen and easily replaced, and that the material of which the piece is made will not cease to be reliable.

The impact test, to which attention was directed at that time in France by M. Considère and later by M. Frémont, seemed to be a very convenient method for ascertaining the characteristics of the parts of each class. The impact test, however, was devised primarily for soft steel and had to be adapted for very hard steel. But by making use of the impact test it was possible to select for the parts of the first class a grade of steel which only fractured after a very small amount of deformation, and this could be considered as a very excellent quality for the parts of this class.

The parts of the second class were expected to bend under the impact test to a very great extent, and it was easy to find wrought iron or mild steel possessing this characteristic, although the reliability of these materials for the use considered is a matter open to discussion. But here again the problem became complicated, because there were those who seemed reluctant to admit that some of the parts had to bend easily under certain circumstances and that a limited amount of toughness was not desirable, inasmuch as the steel maker pretended to have grades of steel uniting in a rare degree ductility with toughness.

The tensile tests of these steels showed a high ultimate strength and a great elongation. The impact test showed that a consider-

<sup>1</sup> Architectural and Industrial Engineer. Consulting Engineer, Schnelder Works. Hon. Mem. Am. Soc. M. E.

Presented at the Annual Meeting, New York, December 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

able amount of energy had been absorbed by the test piece, which gave a great amount of distortion. It is evident that if it had been possible to have a diagram of the impact test, showing at every moment what was the amount of stress corresponding to a given deflection, the matter would have been made very much clearer. But since there was no machine that would give such a

FIG. 1. DIAGRAM FOR COMPARING THE RESULTS OF STATIC BEND AND DROP BEND TESTS

diagram, a substitute was found in a static bending machine registering the amount of energy taken in the deformation process, for it was possible to ascertain that in all the cases which had to

FIG. 2. DIAGRAM FOR COMPARING THE RESULTS OF STATIC BEND AND DROP BEND TESTS

be investigated, the number of kilogram-meters absorbed was practically the same as in a quick bend or in a drop test. So far as the appearance of the fracture was concerned there was no perceptible difference in either case, which showed that the metal which seemed to possess ductility and toughness did not possess these characteristics to the extent believed.<sup>1</sup>

Figs. 1 and 2 are diagrams for comparing the results obtained

by drop tests and quick-bend tests on notched test pieces. In these diagrams the ordinates of curves *A* are proportional to loads corresponding to deflections shown on the abscissa scale. In curves *B* (which are the integrals of curves *A*—ordinates  $y_1, y_2, y_3, y_4$ , etc., being proportional to surface *Y* and so on) the amount

FIG. 3. RESULT OF SHARP SHOCK ON A GLASS VESSEL

FIG. 4. DEVELOPMENT OF THE FRACTURE RESULTING FROM A SHOCK ON A THIN SHEET OF GLASS

FIG. 5. FRACTURE SURFACE IN A SLAB OF GLASS

of energy consumed in the bending test is given for each value of the deflection. The ordinates  $y_1, C_1, y_2, C_2$ , etc., are proportional to the amount of energy absorbed by the drop test for the same

<sup>1</sup> The author has recently learned that the same idea of interpreting a drop test by means of a diagram given by a static bend test has been successfully used in this country for testing rails, and he believes that it can be used in many instances.

FIG. 6 SMALL SPLINTERING FOCUS—GLASS

FIG. 7 SPLINTERING FOCUS—GLASS

FIG. 8 FRACTURE IN JUDEA BITUMEN

deflection, as measured in the bend test, and can be easily compared with  $y_2/y_1$  or  $y_3/y_1$ . The energy absorbed in the drop test appears to be only slightly greater than that absorbed in the quick-bend test, but the process has followed the same course in both cases, and the difference may be attributed to errors in the experimental work.

Fig. 1 is a diagram of a test of wrought iron or mild steel in which the amount of stress necessary to obtain a given deflection remains constant over a long range. This is the type of material which can be expected to give good results for parts of the second class.

Fig. 2 is a diagram of a test of a steel with a certain amount of ductility, in which the energy consumed for a given deflection appears to be greater than in the case of Fig. 1, and which was offered for parts of the second class. It should be noted that in

FIG. 9 FRACTURE IN GLASS

Fig. 2 curve A is absolutely different from curve A of Fig. 1, as it shows that a maximum amount of the energy is absorbed after a small deflection has been obtained. This maximum is the point where the piece begins to show a crack, which of course did not exist in the test piece whose diagram is shown in Fig. 1.

Parts of the second class made of this metal proved a decided failure. Even without experiencing the "normal accidents" which they were expected to withstand, they showed a great tendency to crack without the slightest deformation, which method of fracture has been called *fissillité* by the late M. Brustlein, of the Jacob Holtzer firm, Unieux, France.

By looking closely into the fracture of the broken test piece, which was supposed to possess ductility and toughness, it could be seen that most of the distortion, or flowing of the metal, had taken place not before the fracture was started, but during the process of extension of the fracture, and this gave to the amount of energy recorded an altogether different meaning. In this case

the failure of the material could be traced to a bad interpretation of the test, but other failures were encountered which could not be traced to the quality of the metal used. Typical among these

FIG. 10 FRACTURE IN JUDEA BITUMEN

was the sudden snapping of levers, under conditions which could be specified but which were difficult to explain. The impact test, like others, could not give a clue as to reliability in certain circumstances.

FIG. 12 FRACTURES IN TOOL STEEL

#### THE STUDY OF FRACTURES

The uncertainties in the behavior of material, the propagation of a crack without any distortion of the piece, the sudden snapping of a rod without any perceptible alteration in the neighbor-

FIG. 13 RENTS FORMED UNDER THE MAIN SURFACE IN GLASS

hood, even the changes which were produced in brittleness under heat treatment, appeared to be difficult to account for, and it

seemed to the author to be worth while to add to the theoretical views of the question by making, as far as possible, a thorough study of the fracture itself, which would tell, in some cases, the story of the failure.

It is frequently believed that fracture is a form of failure of such peculiar character as to escape all rules. However, the attention of the author was first attracted by the very regular fractures of sandstone, which is used extensively in France for pavements, and which so resemble one another that they seem to be real diagrams of what has happened during the rupture. Moreover, a certain number of peculiarities of the fractures were found to be common to both sandstone and steel. It was also noticed that these same features were found in glass fractures, in which they could be observed with great accuracy; also that they were still easier to observe in Judea bitumen, where the breakage was produced very easily. A further study has shown that the fractures developed in an identical manner in these various materials.

It is not possible in the limited time at the disposal of the author to go thoroughly into the subject of the study of fractures, and as a result attention can only be called to some of the main features. Fig. 3 shows a fracture developed in a glass vessel by a sharp shock. In this should be noted the symmetry of the surfaces originated and the peculiar disposition of the starting points of these surfaces from both ends of a small line to which the surfaces are tangent. Fig. 4 shows the development of the fracture resulting from a similar shock in a thin sheet of glass. Here great symmetry is seen, the network also originates from a small line, and some of the surfaces extend entirely through the glass, some only partially.

FIG. 11 SCHEME OF FRACTURE IN JUDEA BITUMEN

FIG. 14 SCHEME OF TEARING, WITH CRACKS THAT ACCOMPANY IT

Fig. 5 is taken from a slab of glass broken in the same manner. It shows one of the surfaces dividing the slab into pieces, which was also partially cut by other surfaces. In this particular case the blow was given at *I* on the top of the slab, and it will be seen that the small line, noted in the previous figures as the origin of all the cracks, is situated at *F* at the opposite side of the surface. It presents a very remarkable appearance and the general disposition of the surface induces us to believe that the fracture originated in that region.

Figs. 6 and 7 show in great detail other specimens of very peculiar surfaces, which illustrate very clearly that there is a starting point of the fracture. These examples enable us to see that one of the main surfaces cutting the test sample has not expanded at one stretch, but is formed by surfaces overlapping each other like the blades of a fan. This is made still more evident by the fracture shown in Figs. 8 and 9. These surfaces overlap each other at distances often smaller than a hundredth of an inch, and by making use of the method called *recoupement* (recutting) by the geologists, it is possible to follow the successive order in which the various elements of the fractures have developed.

Fig. 11 shows in greater detail one of these surfaces, and enables us to point out some of its special features. Part of the surface is bright and part dull. A study of the bright part can be made from Fig. 10, which shows a standard fracture in Judea bitumen. It is very easy to follow the surfaces overlapping each other, as is shown by the scheme in Fig. 11. The general arrange-

ment of the surfaces bears a very close resemblance to the surface of water as it runs in a culvert, passes over a dam, or expands in a shallow pond.

The same arrangements of fractures, overlapping surfaces, foci, etc., which are easily observed in glass and Judea bitumen are also met with in tool steel, as shown in Fig. 12.

We find that the dull part gives the impression that it has been rent or torn away, while the bright surface seems to have been carefully cut. Fig. 13 shows how the dull surface is originated by small rents coming from under the surface. If now we come back to the focus of Figs. 6, 7 and 8, and look for the point where it has been originated we find that it also lies under the surface.

Fig. 14 shows what takes place in the tearing of a tough substance such as gelatine. The cracking *bb* travels ahead of the parting at *a* and prepares the way for its advance.

Fig. 15 is another and striking example of the tearing of a tough material. The parting at the edge of the tool has been made possible by a "cracking" similar to that shown in Fig. 14. The sketch in Fig. 16 shows the scheme of the formation of the steel chip.

But how can a bright surface be produced? How can the cutting process be carried on without the sub-surface cracking? How can surfaces be cut which run parallel within such small distance as the ones we have noted? The only explanation which seems to be satisfactory is that the cutting power is a vibratory motion of the surfaces of the fracture, so long as they do not join each other.

FIG. 16 SCHEME OF STEEL CHIP

FIG. 15 OUTLINE OF THE FRACTURE OF A BITUMEN BLOCK

Fig. 17 shows a very typical arrangement of the fracture surfaces in a bitumen block and Fig. 18 gives an outline of the different parts. The same arrangement is constantly found in steel fractures, Fig. 19 showing a similar fracture in a piece of a steel rail broken under a drop test.

#### STRESS AND STRAIN

What are the conclusions to be drawn from this brief study of the mechanism of fractures? How can it pretend to be a contribution to the science of resistance of materials? In a general way, by showing the succession of the phenomena which have taken place during the spreading of the fracture, it affords an experimental proof that the straining effects are more detrimental to the material than mere stress. This is in accordance with what has been shown by a purely mathematical study of the question.

In case of an impact fracture, be it in a piece of glass or in a piece of steel, we find the starting point of the fracture under the surface, although the maximum stress must certainly be located on the surface itself.

In the case of a piece subjected to tension only if a comparison is made with the fractures already considered it will show that fracture has originated along the axis of the test piece (see Fig. 20). The surface of the test piece itself sustains a very important stress, but without being subjected to the strains resulting from the contact of layers undergoing uneven stresses, flowing, so to speak, to give the reduction of area.

The predominance of the internal or straining action is no less

striking in the case of a rent where the straining effect travels in advance of the stress which could be originated at the separating

FIG. 15 STEEL CHIP

FIG. 17 FRACTURE OF A BITUMEN BLOCK

FIG. 19 PIECE OF STEEL TIRE BROKEN IN A DROP TEST point. (See Fig. 14.) This condition should induce the metallurgist to pay more attention to the causes which produce strain-

ing in other words, to the tensions which may exist in the pieces after being cast or forged. This is illustrated by the changes in brittleness which occur in glass undergoing heat treatment. The heat treatment does not bring about any change in its molecular arrangement, but the glass coming out of the furnace is very brittle, and after being properly annealed is so much less so that it is in the so-called unbreakable state; that is to say, it can sustain shocks and bending to a much greater extent than ordinary glass.

The first condition is one of very uneven tension; the second, one without tension; and the third, one which has a beneficial tension.

FIG. 20 TEST PIECE RUPTURED UNDER TENSION: FRACTURE ORIGINATED ALONG THE AXIS

This unevenness of tension also exists in steel, irrespective of the chemical or other changes in structure. An example of the effect of these internal tensions is given by Fig. 21, which shows a fracture in a rail. It is evident that the fracture was started in the neighborhood of the neutral axis, a fact which could not be accounted for if the piece had been under normal conditions:

FIG. 21 TENSION FRACTURE IN A STEEL RAIL.

therefore the causes of a fracture of that kind must be traced to a tension most likely produced in the rolling mill. This case illustrates the mode of cutting which produces bright surfaces in glass, and which can only be explained by the presence of a vibratory motion of the surfaces when they are apart from one another.

In conclusion the author trusts he has created the impression that a methodical study of fractures is of the greatest importance, especially as it leads to a knowledge of the causes of failures which cannot always be attributed to the intrinsic qualities of the metal itself.

## Large Gas-Well Fire Extinguished with Explosives

The successful application of explosives in extinguishing a fire at one of the Standard Oil Co.'s wells near Taft, Cal., reported in a recent issue of the *American Gas Engineering Journal*, suggests the possibility of greatly simplifying the present expensive methods of extinguishing gas-well fires, oil-well fires and oil-reservoir fires.

Drilling operations with a rotary drill were in progress in well No. 7, in the Elk Hills, in the Midway Oil Fields. The well was at a depth of 2135 ft. in 10-in. casing when a supposed water sand was encountered. To test this sand for water the mud in the well was bailed down to relieve pressure and to allow any water present to accumulate in the well. During the course of bailing the well blew out under tremendous pressure and gas began to flow at the rate of 125,000 cu. ft. per min.. An attempt was made to get the well under control by closing a 12½-in. gate valve with which the casing was equipped, but the shale and sand carried by the stream cut out the seat of the valve while the gate was being closed and the well continued to blow. Soon afterward the friction caused by shale and sand had produced a red-hot heat on the casing, and the gas, igniting, burst into a column of fire, gushing 300 ft. skyward. Its maximum width of about 50 ft. was reached after the flame had traveled about 100 ft. upward. The gas emerged from the casing with such force that for a distance of 12 ft. about the casing there was no flame. The derrick, 100 ft. in height, was immediately consumed and all that remained was a twisted mass of iron and steel. Metal at the casing melted, while within a radius of 50 ft. it was raised to a white heat. Everything within hundreds of feet was burned and baked. It is reported that the fire could be seen from a distance of 80 miles and that the roar from the escaping gas could be heard at a distance of ten miles.

Attempts were made to extinguish the fire, first with ten boilers, and subsequently with sixteen and twenty boilers. With the twenty boilers there were twenty-one 3-in. lines and nine 4-in. lines and eleven rotary pumps throwing steam, water, mud and carbon tetrachloride. Nearly half a million dollars were expended in vain attempts to extinguish the fire. In the meantime the casing above ground had blown off, the well had formed a crater and the flame was down to the ground level.

As a last resource it was decided to suspend a package of Giant blasting gelatin upon cables in such a manner that the package could be safely brought to and exploded at the edge of the fire at a distance of about 40 ft. above the ground. Two derricks approximately 40 ft. high were built on either side of the burning well and so far away that the heat would not destroy them. A 9/16-in. steel cable was attached to the top of one of them, then laid around the well outside of the heat zone to the other derrick where it was run through a pulley at the top and the end attached to the drum of a small winding engine underneath. The explosives, bound in one package and covered with heavy sheets of asbestos, were securely attached to this cable at the same distance away from the first derrick as the burning well was. The engine under the second derrick began drawing the cable taut, which pulled the explosives toward the well and at the same time hoisted them. When they had reached the proper spot they were exploded electrically. All of these operations had to be done very quickly so as to bring the explosive charges to the necessary point before they were ignited or exploded by the heat from the burning well.

When the package exploded the fire was divided into three sections. The section at the point of explosion was moved bodily away from the column of gas in a horizontal direction, the upper section was blown upward and beyond danger of re-ignition of the gas column, while the lower section was snuffed out, the flow of gas being temporarily checked.

An idea of the enormous amount of gas flowing from this well may be formed by noting that it could conveniently supply eight cities of the size of San Francisco, which alone consumes 22,000,000 cu. ft. of gas each day.

# Physical Basis of Air-Propeller Design

By F. W. CALDWELL<sup>1</sup> AND E. N. FALES,<sup>2</sup> DAYTON, OHIO

*Description of wind tunnel at McCook Field, Dayton, Ohio; phenomena discovered by its use; analysis of propeller theory and application thereof to fan design in the light of facts established experimentally; methods for visualizing air flow.*

The wind tunnel at McCook Field is notable first for the high velocity of air used (500 m.p.h.) and second, for means adopted to visualize the air flow. This latter is done by maintaining the humidity of the air in the tunnel at a certain predetermined level and by providing opportunities for its condensation where it will show the character of the air flow.

The study of air flow by these means gave new data on vortex formation created by the presence of aerofoils and made it possible to form a clearer conception of the conditions surrounding the operation of propellers.

The value of such investigations as can be made with the McCook Field equipment lies in the fact that hitherto the theory underlying flight phenomena has been purely rational and not directly applicable to engineering design because of the absence of empirical measurement of flight vortices. Because of this, it was impossible to predetermine the performance of aerofoils of new shapes, speeds and sizes without first building a model and determining the particular coefficients applicable to the new design experimentally. Data obtainable in a wind tunnel having provision for visualizing the air flow are, however, capable of supplying this deficiency.

The authors show the application of some of the data obtained to the design of blowers and fans.

MEMBERS of The American Society of Mechanical Engineers as well as most of the older engineering professions have shown a keen interest in aeronautical problems and in the progress of the scientific side of aviation. This interest is no doubt partly due to the romance of seeing realized mankind's age-long desire to imitate the birds in their flight; and partly to the patriotic hope that America will become predominant in a field which owes its existence to two American inventors.

This interest is very valuable to aeronautical engineers, as we feel that association with the older professions ought to enable us to keep at least one foot on the ground. At the same time it is felt that the information gained in aeronautical research may prove helpful in some ways to the mechanical engineers.

It is the purpose of this paper to summarize our conceptions of flight phenomena as developed by the use of the high-speed wind tunnel at McCook Field. The understanding of the fundamental aerodynamical phenomena upon which flight depends has been rather vague throughout the past, simply because of the invisibility of the air. Our knowledge of these phenomena has been based on deductions made from observing the forces produced. (The variation of the air resistance has been well understood for various types of wings, and also for solid bodies of geometrical shape.) To evaluate these forces, however, the results only have been analyzed—not the phenomena themselves. Measurement of the dynamic and static pressures in a given air flow has contributed somewhat to our knowledge of what goes on in the air. The use of threads, solid particles, such as smoke, etc., has also been universal for determining the direction of given portions of an air flow. Such methods, however, have barely scratched the surface of the problem and have been of small value to the aerodynamical analysis of the mathematicians.

A means of actually visualizing the air is therefore of greatest interest; and while its immediate application has been to the specific case of studying air flow past aerofoils, many other uses suggest themselves wherever air in motion constitutes an en-

gineering or scientific factor. Thus, for instance, the study of meteorology involves a knowledge of the circulation of air currents on a large scale over the earth's surface; this knowledge, too, is imperfect because of the invisibility of the medium concerned, and can be greatly improved by application of means for visualization. Moreover, the flow of air in ventilation and other engineering processes is a question which may frequently require analysis by a method of visualization.

It is thought that the general engineering profession will quickly deduce from the experiments recorded in this paper principles which can be of service in their more commercial fields. Therefore it has been our aim to summarize the main features of these experiments without going too deeply into the technical details necessarily of interest only to the aeronautical engineer.

The experiments have resulted in discoveries which may be briefly summarized as follows:

The flow of air, whether in a duct or past an aerodynamic body, is subject to parasite energy losses connected with accidental whirls and eddies, and also to internal motion on account either of

FIG. 1 PHOTO OF TIP VORTEX, CAMERA AXIS BEING COINCIDENT WITH VORTEX AXIS

the shape of the containing duct or the aeronautical body. Analysis of these motions in the air can be facilitated by visualizing them. The writers' method for producing visualization involves condensation of the moisture contained in the air. This moisture, when turned into visible vapor by suitable means, takes up shapes dependent upon the motion and pressure gradient of the air and justifies us in considering that the air itself is thus visible. (See Fig. 1).

When the air is made to flow past an aerodynamic body, special shapes of flow result and can be visualized by our method. It has been shown in our experiments that when the speed changes, the characteristics of the internal motion in the air alter. This alteration has been a source of much uncertainty to aeronautical engineers in the past; but the combination of visual study of these changes of air flow, together with quantitative analysis of the forces involved, has made it possible to throw much light on the underlying structure of the air as it applies to dynamic lift and propulsion.

In our experiments, then, we introduced small wooden wings (aerofoils) into the air current of the wind tunnel and studied their performance; intending to interpret the results for the purpose of propeller design.

## WIND-TUNNEL APPARATUS USED FOR OBSERVING AEROFOIL COEFFICIENTS AND AIR FLOW

The McCook Field wind tunnel (Fig. 2) was designed by the writers for advanced study of aerofoil coefficients used in propel-

<sup>1</sup> Air Service, Engineering Department, McCook Field.

Abstract of paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Advance copies of the complete paper may be obtained gratis on application. All papers are subject to revision.

FIG. 2 McCook Field Wind Tunnel, General External View

lers. It is a departure from the accepted type of wind tunnel in two ways: first, it has a speed higher than elsewhere attained for similar purposes—500 miles per hour at 200 hp.; second, it makes possible the visualization of aerodynamic phenomena.

It seems wise to summarize briefly the general function of a wind tunnel, which is the laboratory apparatus of the aeronautical engineer. An airplane, when once in the air, is very difficult to analyze; neither the pilot nor an observer on the ground is able to gage accurately the speed, angular attitude, nor the air forces acting. So far, no thoroughly accurate instruments for accomplishing full-flight analysis have been perfected. Projects have been proposed for attaching a full-sized airplane to a moving electric locomotive properly equipped to record accurately all the forces produced; but such a plan has drawbacks. It is found that the best, most accurate and cheapest way to analyze airplane characteristics is by means of the wind tunnel. This is a confined artificial blast of air which is made to blow against a model wing or airplane. The model is supported in the air blast by a thin rod reaching into the wind tunnel from outside, where it connects to a delicate scale. Thus all forces created on the model are transmitted to the scale where they can be measured.

It is found that the forces due to the air current blowing against fixed objects are the same as though the object were moved through still air, provided the air current is smooth and without eddies. Elimination of eddies is therefore an important requirement in a wind tunnel.

The forces found in a wind tunnel apply to full-sized machines, and wherever aeronautical design is carried on the wind tunnel is essential. Besides the McCook Field wind tunnel there are in America about a dozen others. In Europe there are many more, the British National Physical Laboratory employing seven. The largest in existence is now being built at Paris, 13 ft. in diameter and of 1000 hp. capacity. The typical wind tunnel has a stream of air 15 to 50 sq. ft. in cross-sectional area, flowing at a velocity of from 30 to 90 miles per hour.

#### THE QUESTION OF WIND-TUNNEL SPEED

The speed and size of a wind tunnel have a recognized importance in the interpretation of the results obtained. The usual coefficients of aeronautical engineering are determined by tests on a model aerofoil of from 3 to 6 in. chord at velocities of 45 to 130 ft. per sec. The data obtained must be applied in the full scale of areas a hundredfold greater in the case of wings, and to velocities ten times greater in the case of propellers. There may be a discrepancy between model and full-scale coefficients, and this is spoken of as "scaling effect."

*Scaling Effect.* While scaling rules and empirical factors worked out in practice have enabled us to produce very fair results, there is decided room for improvement. Indeed, so meager is the available information on the scaling effect, as treated under the "law of dynamic similarity," that a growing tendency has appeared among aeronautical engineers to regard

FIG. 3 CHART OF VELOCITY TRAVERSES FOR VARIOUS INTAKES

the classical coefficients  $K_x$  (coefficient of drag) and  $K_y$  (coefficient of lift) as inadequate.

It has been almost universally the practice to write

$$L = \frac{\rho}{2} g K_y A V^2 \\ D = \frac{\rho}{2} g K_x A V^2$$

where  $L$  is the lift (vertical lifting force),  $D$  the drag (resistance),  $A$  the area of the supporting surface,  $V$  the velocity of advance,  $\rho$  the density of the air in weight units,  $g$  the acceleration due to gravity, and hence  $(\rho/g)$  the density of the air.

It is well known as the result of experience that the values of  $K_x$  and  $K_y$  vary somewhat with velocity and also with the size of the surface under consideration. If  $l$  represents one of the linear dimensions of the surface and  $\nu$  the coefficient of kinematic viscosity, it is assumed, according to the law of dynamic similarity, that values of  $K_x$  and  $K_y$  are functions of  $Vl/\nu$ . Since  $\nu$  is usually considered constant, it is customary to compare the product  $Vl$  for experiments in a given medium.

The wind tunnel designed by the writers permits the attainment of a  $Vl$  product of 60 ( $V$  in ft. per sec.,  $l$  in ft.). While this figure is twenty times less than the corresponding full-sized wing values, it is only four to eight times less than full-sized propeller values.

As a matter of interest, tip speeds of some of the propellers in actual use are given below:

Airplane	Engine	M.p.h.
USD-9	Liberty-12	650
VE-7	Hispano-Suiza, 150 hp.	545
Thomas-Morse	Le Rhone, 80 hp.	380
Verville Chase	Hispano-Suiza, 500 hp.	600
Roché XB-1A	Hispano-Suiza, 300 hp.	625
Curtiss JN-4	Curtiss OX-5	420
DH-6	Rolls-Royce, 375 hp.	450

It would be ideal if a wind tunnel could be built large enough for testing propellers and airplanes of full size and speed. Such apparatus would, of course, be enormous and of prohibitive cost. We must therefore be content with wind tunnels whose  $Vl$  product is smaller than the full-flight value. In designing a tunnel

FIG. 4. DIAGRAM SHOWING EDDIES IN CONE OF TOO LARGE ANGLE

we may have either large size and low speed, or vice versa. In general a large wind tunnel requires a large, expensive hall, while a high-speed tunnel requires high horsepower.

Thus in the McCook Field wind tunnel we have attained a velocity equal to full-flight values, and the size of model is correspondingly small. The results obtained, however, demonstrate greater significance than were the same  $Vl$  product obtained with a larger model and smaller velocity. By means of the high velocity, discoveries of outstanding importance have been made, namely, the means of visualizing flight vortices, and the identification of changes in these vortices with simultaneous changes in the aerofoil coefficients.

#### DESCRIPTION OF THE MCCOOK FIELD WIND TUNNEL

The tunnel has the form of a venturi tube 18½ ft. long, built of turned laminated wood. Its proportions and novel features have been the subject of exhaustive investigation and experiments on scale models.

**Intake Bell.** Thus the intake bell has a radius of curvature of

15½ times the throat diameter, such as best to take care of the *vena contracta* and insure best velocity distribution and parallelism in the air flow (see chart, Fig. 3).

**Throat.** The throat is unusually short—1.3 diameters—with resulting economy of power. The short throat and the location of the model close to the intake are justified by the study of the

FIG. 5. MCCOOK FIELD WIND TUNNEL, SHOWING OPERATING PANELS

chart in Fig. 3, and are made possible by the elimination of the usual "honeycomb" and by proper intake-bell design.

**Expanding Cone.** The cone leading from throat to fan has an angle of 7 deg., the maximum value established by Eiffel. We have found that in cones of larger divergence the air flow does not fill the cone, a space of whirling and eddying air being left between the blast and the containing walls (see Fig. 4), with resultant loss of energy. The principle involved is that flowing air surrounded by solid walls loses less energy by surface friction than if surrounded by inert air.

**Straighteners.** To eliminate velocity fluctuations a novel straightener is used—the conventional "honeycomb" being eliminated. The straightener is placed 4 ft. down the cone and has four radial blades 4 ft. long, so located as to prevent inflow whirl by obstructing the formation of the pressure apex. An auxiliary straightener (Fig. 5) with flat radial vanes is located outside the intake; and together the two reduce velocity fluctuations from 15 per cent to 3 per cent, without appreciable power loss.

#### POWER PLANT AND FAN MEASUREMENTS

Velocity is measured in terms of dynamic head minus static head. For measuring dynamic head there is an "impact" tube at the throat somewhat off the center of the tunnel axis. For measuring static head a perforated plate is used, set in flush with the walls. A differential manometer records the velocity head, the whole apparatus being analogous to the conventional pitot tube and Krell manometer.

Temperature of the air passing through the throat is calculated on the assumption that expansion is adiabatic from atmospheric pressure to pressure corresponding to condensation, and is polytropic below the latter pressure. Correct knowledge of throat temperature is, of course, essential, and it is necessary to develop a special method of thermometry for reading it. Present methods are inapplicable to its direct measurement, for a thermometer introduced into the air stream occasions more or less adiabatic compression of the air striking it, with consequent rise

of temperature at the point of impact. (See chart, Fig. 6.) The most advantageous position for the thermometer is with the bulb down stream, where it is subject chiefly to skin friction rather than impact. Further investigations are being made of the matter.

The balances are of two types. The first one measures lift and drag on two separate instantaneous reading Toledo scales

FIG. 6 CHART OF THEORETICAL AND MEASURED TEMPERATURES

and is mounted upon a portable carriage (see Fig. 7). The spindle for the model projects horizontally and axially from this carriage into the mouth of the wind tunnel, carrying the model at its free end. The spindle terminates in a thin flat bar, the latter clamping a graduated disk which is rigid with the model at the center of the span. Three advantages of this type of balance are: (1) That instantaneous readings make it possible to synchronize balance and velocity observations and to practically eliminate the effect of velocity fluctuations; (2) The air forces can be qualitatively studied; as, for instance, in the case where a given setup has two values of  $K_D$  or  $K_z$ . The balance can then be seen to change from one reading to another; (3) The method of support affords a highly accurate means of skin-friction observation.

The conventional supporting spindle, as adopted at the National Physical Laboratory, cannot be utilized under the conditions of these tests. In order to definitely delimit the effect of the supporting member, further developments are proposed where this effect will virtually be eliminated from the tests. The effect of the center support on the lift coefficient is not considered serious. This conclusion is based on experiments run at other laboratories where the effect of the support has been determined; also on a comparison of the present series of experiments with tests made elsewhere on a larger model supported at the end, for the same  $V$  values. The effect of the center support on drag, however, is known to be large; the air-flow disturbance is visualized in Fig. 8, where it appears as a white tuft above the support.

**Power Plant.** The power plant consists of a Sprague dynamometer, capable of delivering 200 hp. for one-half hour at 250 volts and 1770 r.p.m. without overheating. The 5-ft. fan (Fig. 9) is made with a solid-center disk 40 in. in diameter, and has 24 blades 10 in. long. At the upstream side of the 40-in. disk a bell of equal diameter is fixed in the tunnel so that the air is let up to the annular discharge opening with a minimum of eddies. The operating efficiency of the whole tunnel is 75 per cent higher than has been usual for the determination of aerofoil coefficients in other wind tunnels. By efficiency is understood the ratio of kinetic energy of air stream at throat of tunnel,

minus the energy absorbed by the fan, all divided by the energy of the air stream at the throat.

Careful study of fan and cone design questions not only in reduced losses but also in reduced noise. The question of noise has in the past been a serious objection to speeds greater than 70 miles per hour in wind tunnels. The roar of the fan is analogous to that of an airplane propeller, which usually makes more noise than does the unmuffled motor exhaust. For wind-tunnel use the combination of fan and cone adopted has brought about a considerable improvement, as indicated in the following tabulation:

Fan is noiseless at.....	50 m.p.h.
Starts to roar at.....	60 m.p.h.
Conversation easy at.....	125 m.p.h.
Conversation slightly forced at.....	155 m.p.h.
Possible 12 in. apart at.....	240 m.p.h.
Possible 4 in. apart at.....	300 m.p.h.

From the operator's position:

**Fan.** The fan represents a very interesting union of airplane-propeller principles and blower-design principles, combining the high pressure usually associated with centrifugal blowers with the high efficiency of the airplane propeller. While essentially a propeller fan of aeronautical design, its 16-in. pressure head is such as would ordinarily be expected only from a centrifugal blower.

This application of airplane-propeller principles to blower design is significant to the ventilation engineer, who may by such means produce in wood, at comparatively small cost, blowing apparatus of high efficiency, high horsepower, high head, and reduced noise.

#### APPLICATION OF PROPELLER DESIGN TO COMMERCIAL USE

As a further illustration of the benefits to the ventilation engineer of airplane-propeller principles, the following may be cited as of interest:

FIG. 7 McCook Field Wind Tunnel, Balances and Intake

It has been found possible, by impressing special properties, to extend the usefulness of one of our most common and universal devices—the electric cooling fan. In the ordinary electric cooling fan referred to, the air flow is analogous to that of an airplane propeller rotating at a fixed point on the ground, and is shown in the sketch, Fig. 10-1.

The blast converges as it leaves the blades, reaching a maximum velocity a short distance from the fan, and gradually dis-

sipating its energy as the flow lines expand along a small-angle cone. Thus, in such a blast the energy is concentrated in a narrow stream. Numerous experimenters have conceived the idea of placing vanes in front of these fans to diffuse the air and make it spread outward, but no practical success has been secured.

The problem is one of many minor ones which have found their solution as a side issue to the war activities of the Air Service. By judicious application of aerodynamic principles, a cooling fan has been developed which delivers a fan-shaped expanding blast, while moving as much air as the older conventional type of fan. See sketch, Fig. 10-B.

This fan directs its stream, not along a single axial line, but along a sector embracing 90 or even 180 deg. The advantages are obvious:

*First*, the energy of the blast is rapidly dissipated over a large area, causing a large, gentle circulation in place of a small, violent one.

*Second*, the blast spreads over an angle equal to that attained by the conventional oscillating type of fan, and accomplishes the same beneficial results without the unpleasant features associated with intermittent action.

*Third*, such a fan can produce a truly conical blast of which the fan-shaped expanding blast is only a special case; thus, the advantage of large cross-sectional area is secured from a small high-speed fan; and for purposes of overhead or ceiling use such a device is considerably cheaper than the conventional low-speed, large-diameter ceiling fan.

*Fourth*, the device involves only a simple, inexpensive addition to the conventional fan, may be readily applied to it, and causes no additional noise.

#### VISUALIZATION OF FLIGHT VORTICES BY THE WRITERS' METHOD

The method of visualizing air flow discovered by the writers together with C. P. Grimes offers a solution of the fundamental problems of aerodynamics. This problem is the quantitative empirical measurement of the phenomena of fluid dynamics as applied to flight and air flow.

The accepted theory upon which flight has its physical basis is purely rational. It has not yet been directly applicable to engineering design, because empirical measurement of flight vortices has never been made. Therefore, the aeronautical engineer's

coefficient of force on a small model of this wing to an accuracy of 1 per cent. But we do not know definitely how the accuracy is changed by scaling up to full size, or to full speed. We cannot, without tests, predict the change of coefficient to be expected when the wing shape is altered, or the angle of attack, or the position with reference to other surfaces.

Aerodynamical theory will serve practical use when supported by empirical data. In the past, flight vortices have never been

FIG. 9 McCook Field Wind Tunnel, Fan End

measured, nor even visualized to a usable extent. Analysis of air flow has been confined to the use of smoke or powder set loose in the air to indicate lines of flow; or of threads used as wind vanes. Or we have been driven to analogies derived from study of fluids of different viscosities and densities, such as water. Or, further, we have sought by measurement of static pressures in the air surrounding a body to deduce the lines of flow. But these methods have given small encouragement to the practical application of the vortex theory to engineering use.

The writers' method bids fair to supply the missing link between aerodynamical theory and design. It depends upon the fact that the moisture in the air condenses out as fog when the temperature is reduced to the dewpoint, provided there is a solid or liquid nucleus to start the condensation. In the McCook Field wind tunnel the temperature drop is brought about through expansion of the air during acceleration due to 100 in. of water suction. Relative humidity of the atmosphere can be artificially raised if too low. The necessary nucleus for condensation is provided by the model itself.

Flight vortices become readily visible by the writers' method and can be photographed with the aid of searchlights. Several efforts were made to take the pictures with a plate camera but these were not very successful. Finally a good moving picture was taken and some of the films enlarged. While these films showed up very well on the screen the detail was not very clear in enlargement, so that, in addition to the searchlights which were provided with nitrogen-filled incandescent lamps, two carbon arc lights were set up in order to give a greater amount of blue light. The results obtained from the motion-picture camera with the carbon-arc lighting were fairly satisfactory, and a number of enlargements from the motion-picture films are reproduced in this paper. Fig. 1 is an enlargement of a moving-picture film looking downstream, and shows the left half-span of a small model aerofoil, with tip vortex trailing downstream from the tip and edge vortex-sheet below the model. The edge vortex-sheet is made up of vortices with axes parallel to the rear edge of the model; they build up and run off at such frequency as to appear continuous. It is somewhat inferior to visual observation. To the naked eye the tip vortices are in line with the wing tips

FIG. 8 Tip Vortex, High-Lift Régime

use of aerodynamics is largely according to the cut-and-try method. He cannot, on the drafting board, depart from known shapes, speeds or sizes without first building a model and determining the coefficients applicable to his new design.

To illustrate this point it is only necessary to refer to the simplest case, that of an airplane wing. We can measure the

and are clean-cut, perfect circles. They extend downstream a distance of several dozen chord lengths from the rear corner of each wing tip, enlarging in diameter as the distance increases, and converging slightly in the horizontal plane (see Fig. 11). In the vertical plane the tip-vortex axis takes a decided downward angle, intermediate between the horizontal and the line of the flat sheet of edge vortices.<sup>1</sup>

At slow speeds condensation is not obtainable, but the vortex phenomena can be corroborated by injecting a jet of visible steam into the air current. Such a jet, when of proper saturation, affords a better indication of flow direction than does smoke or thread.

Adequate analysis of the flight vortices is now being made with stroboscopic apparatus. The shape, size and direction of the

FIG. 10A AIR FLOW THROUGH TYPICAL ELECTRIC FAN

FIG. 10B AIR FLOW THROUGH MODIFIED ELECTRIC FAN

tip vortices can be easily noted and seem fairly susceptible of measurement. The periodic run of the edge vortices is too quick for recognition by the naked eye, or even for identification by the moving-picture camera; it requires stroboscopic analysis.

The observed vortices differ for different aerofoil setups and different speeds. For instance, the observed tip vortex at 18 deg.

FIG. 11 PLAN VIEW OF FLIGHT VORTICES

has less than one-half the diameter manifest at 8 deg., while the line of edge vortices is less noticeable at 18 deg.

Again, the character of the general vortex phenomenon undergoes remarkable change at the critical speed. In the high-lift régime the general shape is like a trough whose floor (edge

<sup>1</sup>For an excellent mathematical discussion of the shape and arrangement of the tip vortices and the trailing vortices, see report No. 28 of the National Advisory Committee for Aeronautics (U. S.). On page 44 the author, Dr. George de Bothezat, has shown in an interesting way that the axis of the tip vortices is intermediate between the direction of movement and the sheet of trailing edge vortices.

vortex-sheet) slopes downward from the trailing edge, and whose walls (tip vortices) are increasingly high as the distance downstream increases. The cross-section is roughly like a shallow U.

At higher speeds, however, in the low-lift régime, the observed phenomenon is suddenly altered. Following out the above homely analogy, we may imagine that the "walls" of the trough remain substantially as before. The "floor," however, splits longitudinally, curls upward, and extends the two limbs, now free, to a point well above the level of the tip vortices. This is shown

FIG. 12 DIAGRAM OF HIGH- AND LOW-LIFT VORTICES

in enlargements of two motion-picture exposures which were intended to record the sequence of the change. These photographs, however, were not altogether satisfactory, and are therefore replaced by the two sketches of Fig. 12.

Fig. 12-A is a diagram of the end view of the high-lift phenomenon as it appears distinctly to the naked eye. The right-hand side of the aerofoil in Fig. 8 approximates this condition, the left-hand side having already gone over to low-lift flow. Fig. 12-B is a diagram of the low-lift phenomenon; the left-hand side of the aerofoil shows this fairly well, the right-hand side being in transition stage. Fig. 11 is a three-fourths view of the low-lift flow, and also represents other features mentioned above.

An interesting variation of the flight vortices is furnished by replacing the aerofoil by a flat disk normal to the wind. Here the phenomenon can be seen as a "stream-line" fog surface, converging towards a point half a dozen diameters downstream.

Fig. 8 illustrates the distance above the aerofoil to which the flight-vortex phenomena may extend, and shows their tendency to merge with other whirls attributable to the wind-tunnel walls. The extent of the phenomenon may be four or more chord lengths above the aerofoil; this further develops a discovery made by the writers in 1911, when it was shown experimentally that the air flow above a wing is disturbed to a distance of at least four chord lengths.<sup>1</sup>

#### VISUALIZATION OF UNOBSTRUCTED AIR FLOW

When the model is removed the vortices and eddies of flow through the unobstructed throat may be observed by looking into the intake or through the transparent shield of the observation section. The condensation is more pronounced behind the impact tube and thermometer bulb than elsewhere, since these are obstacles to the flow and therefore constitute nuclei for condensation. A projecting cotter pin  $\frac{1}{16}$  in. high at the wall causes a perfect vortex, which shows up against the white, foggy background as a black circle.

The general appearance of the air flow, which may be considered typical of all air flow, is as follows: A cross-section at the throat shows a seething mass of fog speckles, denser at the

<sup>1</sup>See The Center of Pressure Travel on Airplane Surfaces and Birds' Wings, Mass. Inst. of Technology, 1911. Reference may also be made in this connection to the work of J. R. Pannell, dealing with experimental evidence as to the extent of circulation about an aerofoil.

wall than at the center, though occasionally the entire disk fills up with fog to the point of opaqueness. The spectators have in the cross-sectional plane a gentle movement like the flame of an alcohol stove, showing the constant readjustment of equilibrium. Vortices and S-shaped whirls continually form and, after moving about, lose themselves in the general confusion. In a diagonal view they take the appearance of long, foggy fibers, stretching down the tunnel like wooden moldings. The axes of whirl, of course, are longitudinal. Under proper humidity and lighting conditions the whole becomes a beautiful iridescent sight, violet and purple hues predominating.

**Lift Coefficients.** Coefficients of lifting force and resistance have been determined for a series of model aerofoils 6 in. long, 1 in. in chord length, camber varying from 0.08 to 0.20. The cross-sectional shape is that upon which the Engineering Division

dynamic phenomena resulting from air flow past a solid body. When the speed of air flowing past an aerofoil increases, there is first a régime of relatively low-lift effect, then at higher speeds an efficient lift effect such as applies in flight, then at still higher speeds a drop back to a second low-lift effect. As the angle of camber increases, the high-lift régime becomes discontinuous and is succeeded by the low-lift régime; the transition point is spoken of in conventional graphs as the critical, or stalling angle, or the "burble point."

All of the sections show, at certain angles, two speeds at which the flow is unstable and discontinuous. At the point of discontinuity occurring at the lower speed, increase of speed shows an increased lift coefficient and a decreased drag coefficient so that the lift-drag ratio ( $L/D$ ) is enormously increased. At the point of discontinuity occurring at the higher speed, increase of

FIG. 13 CHART OF LIFT COEFFICIENTS OF 0.12 CAMBER AEROFOIL.

has standardized for propeller use. A chart of lift coefficients for one of these aerofoils (0.12 camber) is presented, and shows the variation of lift coefficient over the entire range of speeds and angles tested. See Fig. 13.

The outstanding conclusion to be drawn from the tests is that we have more than one régime of air flow to deal with in aerofoil study, and that these régimes are separated by conditions of discontinuity. The characteristics usually associated in aeronautical engineering with a practical aerofoil do not apply outside the small range of cambers, speeds and angles utilized in flight. Beyond this range the flow about the aerofoil no longer produces the familiar results in terms of lift and drag but becomes analogous to the flow about a body of irregular shape. Efficient lift of an aerofoil is only a single case of several distinct aero-

speed shows a decreased lift coefficient and an increased drag coefficient, so that the lift-drag ratio is enormously decreased. Thus these sections have a definite speed range, at each angle, within which the flow is efficient and produces a high lift-drag ratio, and a fairly constant lift coefficient. It may be called the régime of high  $L/D$ , and includes the phenomena appertaining to practical flight. This speed range has been definitely measured for the higher angles, but apparently it goes beyond the speed obtainable in the tunnel for the lower angles.

It will be noted that the  $K_v$  curves are drawn discontinuous to correspond with discontinuity in the type of air flow. In some cases the graphs show a third curve intermediate between the high-régime curve and the low-régime curve. This third inter-

(Continued on page 260)

# Simplification of Venturi-Meter Calculations

By GLENN B. WARREN,<sup>1</sup> SCHENECTADY, N. Y.

In this paper the author describes a method which he has devised for the simplification of the calculations involved in the venturi-meter measurement of the flow of compressed air, and which reduces the work of one determination to a simple slide-rule computation requiring but a few settings. The method, which is described in considerable detail, is based on the venturi-meter formula as given by Herbert B. Reynolds in *Trans. Am. Soc. M. E.*, Vol. 38, p. 799, and can be easily applied to any venturi meter used for the measurement of a gas.

DURING the winters of 1918 and 1919 the writer had occasion to measure with considerable accuracy the amount of compressed air used in connection with some research work which was being carried on at the University of Wisconsin. The venturi meter presented itself as the logical method, but aside from the mechanical difficulties of building manometers to satisfactorily stand pressures of more than 100 lb. per sq. in. the difficulties presented by the calculations where several hundred volume determinations would have to be made

The venturi-meter formula is given by Dr. Lucke as follows:

$$W = CA_1 \left( \frac{P_1}{P_2} \right)^{\frac{1}{n}} \sqrt{2g \frac{n}{n-1} \frac{P_1}{V_1} \left[ 1 - \left( \frac{P_2}{P_1} \right)^{\frac{n-1}{n}} \right] \dots} \quad [1]$$

where  $W$  = weight of vapor or gas passing per second

$C$  = coefficient

$A_1$  = area of entrance

$A_2$  = area of throat

The units in which  $W$  is expressed are dependent, of course, upon the units used in all the other quantities of the formula.

Herbert B. Reynolds in *Trans. Am. Soc. M. E.* for 1916, p. 799, gives the following formula, which can be derived from Equation [1] by the substitution of the proper units:

$$Q = C \frac{3514 A_1 T_s}{P_s} \sqrt{\frac{n}{(n-1)G}} \left( \frac{P_1}{\sqrt{T_1}} \right) \left( \frac{P_1}{P_2} \right)^{\frac{1}{n}} \times \sqrt{\frac{1 - \left( \frac{P_2}{P_1} \right)^{\frac{n-1}{n}}}{1 - \left( \frac{A_1}{A_2} \right)^2 \left( \frac{P_2}{P_1} \right)^{\frac{2}{n}}}} \dots [2]$$

where  $Q$  = cu. ft. per min. at 32 deg. fahr. and 14.7 lb. per sq. in.

$C$  = coefficient (experimentally determined)

$A_1$  = area of entrance, sq. ft.

$A_2$  = area of throat, sq. ft.

$T_s$  = absolute temperature of standard air = 492 deg. fahr.

$P_s$  = absolute pressure of standard air = 14.7 lb. per sq. in.

$n$  = constant =  $C_p/C_v$  (= 1.402 for air)

$G$  = specific gravity of gas (= 1.0 for air)

$P_1$  = pressure of air at entrance, lb. per sq. in. absolute

$P_2$  = pressure of air at throat, lb. per sq. in. absolute

$T_1$  = temperature of air at entrance, deg. fahr. absolute.

3514 = constant determined by above choice of units

The *Sibley Journal of Engineering* (vol. 29, pp. 90-95) presents this formula in still another form, which has been derived by means of the Fourier series and is in better shape for calculation, where the ratio  $(P_2/P_1)$  is very nearly unity, or in other words, for low rates of flow. This formula is:

$$W = CA_1 \left( \frac{T_s 2gn}{V_s P_s (n-1)} \right)^{\frac{1}{2}} \frac{P_1}{\sqrt{T_1}} \left( r \left[ \frac{n-1}{n(1-a)} \right] \right)^{\frac{1}{2}} \times \left( 1 - \frac{[3+a]x}{2n[1-a]} \right)^{\frac{1}{2}} \dots [3]$$

where  $V_s$  = volume under standard conditions = 12.38 cu. ft. per lb. for air;  $a = (A_1/A_2)^2$ ; and  $x = \Delta P/P_1$ , where  $\Delta P = P_1 - P_2$ ; the other symbols being the same as before.

Any one of these three formulae presents a rather difficult computation as far as solution is concerned, this being especially the case in formula [1] and [2] because of the last radical. The log-log slide rule enables the solution to be made quite readily, excepting for values of  $P_1/P_2$  greater than 0.98, after which it is necessary to resort to very complete logarithmic tables, or else to the third formula.

FIG. 1 FLOW CURVES FOR 1.6-IN. X 0.498-IN. VENTURI METER

were of considerable importance. Accordingly, a method of shortening the calculations was devised which reduced the entire work of one determination to a simple slide-rule computation, requiring but a few settings, and which at the same time did not affect the accuracy to any appreciable extent. Although the method of shortening these computations may seem somewhat laborious in itself, when it is remembered that with but a few changes it can be applied to any venturi meter used for the measurement of a gas, the result can be seen to have abundantly justified the means.

<sup>2</sup>25 North Ferry Street.

## METHOD USED TO SIMPLIFY COMPUTATIONS

The first step in the process of reducing these formulae to forms which could easily be handled consisted in determining the values of  $A_1$  and  $A_2$  which would give a venturi meter having the desired range of capacity without making the difference between  $P_1$  and  $P_2$  either too great or too small for easy and accurate reading. In this series of tests it was necessary to have a range of capacity from 25 to 250 cu. ft. of free air per min. at a pressure in the venturi tube of about 100 lb. per sq. in. gage. Inasmuch as the flow is nearly proportional to the square root of the pressure

FIG. 2 CALIBRATION CURVE FOR 1.6-IN. X 0.498-IN. VENTURI METER

difference, as can be seen from formula [3], a range of possible rates of flow of 10 to 1 means a range of readable pressure differences of nearly 100 to 1 in magnitude. This necessitated the combination of a mercury and a water manometer, which will be described later.

It was found by a trial and error method that a venturi meter having an entrance diameter of 1.6 in. and a throat diameter of 0.5 in. would answer the requirements. As actually constructed, the throat diameter was found to be 0.498 in. This gave a ratio of  $A_1/A_2$  nearly equal to 0.10.

Upon substituting these numerical values for  $A_1$ ,  $A_2$ ,  $P_2$ ,  $n$ , and  $G$  in formula [2], there is obtained the following expression:

$$Q = 297.6C \left( \frac{P_1}{\sqrt{T_1}} \right) \left[ \left( \frac{P_2}{P_1} \right)^{0.714} \sqrt{\frac{1 - \left( \frac{P_2}{P_1} \right)^{0.286}}{1 - 0.01 \left( \frac{P_2}{P_1} \right)^{1.43}}} \right] \dots [4]$$

It can be seen that the part in brackets is independent of everything but the ratio  $P_2/P_1$ ; in other words, it is a function of this ratio. Then if we let

$$f \left( \frac{P_2}{P_1} \right) = \left[ \left( \frac{P_2}{P_1} \right)^{0.714} \sqrt{\frac{1 - \left( \frac{P_2}{P_1} \right)^{0.286}}{1 - 0.01 \left( \frac{P_2}{P_1} \right)^{1.43}}} \right] \dots [5]$$

and plot a curve of  $f(P_2/P_1)$  as ordinates against values of  $P_2/P_1$ , it follows that the finding of  $Q$  will merely amount to multiplying several known quantities on the slide rule, since  $f(P_2/P_1)$  can be found from the curve, thus:

$$Q = C \frac{297.6P_1}{\sqrt{T_1}} f \left( \frac{P_2}{P_1} \right) \dots [6]$$

In practice it is the quantity  $P_1 - P_2 = P$  which is measured by the manometers, and the most accurate method of finding  $P_2/P_1$  from this is as follows:

$$\frac{P_2}{P_1} = \frac{P_1 - \Delta P}{P_1} = 1 - \frac{\Delta P}{P_1} \dots [7]$$

It can easily be seen that this last expression can be evaluated much more accurately on the slide rule than can the second.

The values of  $f(P_2/P_1)$  for values of  $P_2/P_1$  from 1.00 to 0.90 are given in Table 1 and are shown plotted out in the form of a curve in Fig. 1. The values of  $f(P_2/P_1)$  for values of  $P_2/P_1$  between 0.98 and 1.00 were found by evaluating the last two parentheses in formula [3]. It is rarely advisable to use a gas

FIG. 3 ARRANGEMENT OF MANOMETERS, PIPING AND VALVES

venturi meter at values of  $P_2/P_1$  less than 0.90, inasmuch as the total drop in pressure across the meter becomes too great, and also because the reserve or overload capacity of the meter is so greatly restricted. This set of values is worked out for a ratio of  $A_1/A_2 = 0.10$ , but the effect of a slight change in this ratio upon the values of  $f(P_2/P_1)$  is so slight that these values may be used for meters having a ratio differing considerably from 0.10. However, a set of values can be worked out for a tube having a ratio other than this.

The family of curves shown in Fig. 1 was worked out to facilitate rapid slide-rule calculation of the flow during a test. In order to plot these, the temperature in formula [6] was transposed to the left-hand member, thus:

$$Q\sqrt{T_1} = 297.6CP_1 f \left( \frac{P_2}{P_1} \right) \dots [8]$$

and curves for numerous values of  $P_1$  plotted against values of  $f(P_2/P_1)$

# Tight-Fitting Threads for Bolts and Nuts

By CHESTER B. LORD,<sup>1</sup> ST. LOUIS, MO.

*Although in general the thread forms now in use are quite satisfactory, perfection has by no means been reached. There is still considerable search for what the author of the following paper terms "a thread that will not loosen," and in the preliminary portion of his paper he discusses the fundamental principles involved in the manufacture of threads. The problem to be solved, he states, is as follows: "Without sacrifice of strength, without increase of rejection, without additional manufacturing costs, find a method whereby a male and female thread of the same lead and pitch diameter may be made after repeated loosening to fit tight without the aid of a locking device." The reasons for departing from accepted practice are presented and discussed, and as a result of experimental work, the author draws the following conclusions: (1) The cause of stripped threads is lack of room into which the metal can flow; (2) the pitch diameter should be the same in both threads; (3) The lead should be the same; (4) The thread angle should differ by not more than 10 deg.; (5) The limits for the inside diameter of nut need not be adhered to closely, as the inner part of the nut thread holds very little, if any; (6) The outside diameter of plug and pitch diameter of both plug and nut are important and should be adhered to fairly closely.*

**W**HAT is the cause of our periodic dissatisfaction with threads when in general they are so satisfactory? What other machine element is so easily made or is so satisfactory as regards strength? Why are there so many different kinds of threads when all are equally satisfactory, or rather unsatisfactory? Furthermore, is the dissatisfaction founded on performance or merely upon theory? Also, is the form or angle of thread a matter of importance, or merely an excuse for mathematical gymnastics? The only answer the writer has been able to elicit in reply to these various questions is that we are looking for a better thread; which statement, however, is rather indefinite and usually simply means a thread that will pass the gage. Of course, the real object of the search has been to find a thread that will not loosen.

In the past we have attributed our troubles to the fact that our fits were not close enough—the engineer's alibi for a poor design, but fundamentals cannot be violated in mechanics any more than elsewhere in nature, and we are attempting to violate two by insisting upon our present methods of inspection: (a) that interchangeable manufacture is a matter of percentage, which depends upon tolerance and cost; and (b) that a force fit is not possible between two parts the surfaces of which are complements one of the other.

Having in mind the first fundamental, it is obvious that the chances of securing a perfect fit are limited by the cost, and the second fundamental would seem to render this entirely hopeless. It is therefore proper to conclude that a good fit is usually due to error, and that if changing both male and female threads produces no relative change, changing one thread must of necessity do so. It is the object of this paper to demonstrate that by making this latter change threads can be produced that are interchangeable practically regardless of tolerance, that will not loosen, and are cheap to manufacture.

A physician always diagnoses a case before prescribing, so let us do likewise. The loosening of a thread fit is caused by vibration or repeated shock, the chief result of which is to flatten and burnish the parts of the thread that are in contact. This produces a slight looseness and the nut tends to follow the thread incline until it again fits. The same performance is repeated until finally the nut reaches an obstacle too large to flatten, or else the bolt and nut vibrate in unison and there is no further

relative movement. This same phenomenon occurs in the case of a bolt screwed in a tapped hole.

The writer can remember in his shop days picking out and numbering nuts and bolts, and every mechanic knows that he cannot take the bolts out of a cylinder head on an engine of good make and put them back again indiscriminately. They must go back into the holes from whence they came. All have demonstrated to their satisfaction the fact that a tight thread will not loosen by vibration, and that one with tolerance will, unless it is prevented from loosening by a lock washer or its action is limited by some type of nut lock. We cannot lessen our tolerance because the tap wears small and the die wears large, and the lesser cannot contain the greater.

## THE PROBLEM TO BE SOLVED

To gain a better conception of the problem to be solved, consider a board cut as shown in Fig. 1. We cannot obtain a forced

Fig. 1

Fig. 2

Fig. 3

FIGS. 1-3 APPLICATION OF PRESSURE IN THREAD FITS

fit between the two pieces because one surface is the complement of the other. If we apply a force to *A*, we are no better off because the pieces cease to fit the instant the pressure is released. We may therefore state as a rule that where two surfaces are complementary to one another a tight fit cannot result without some means of maintaining pressure. But if we cut the board as shown in Fig. 2, theoretically removing no material, we can replace *A* without force, and any pressure exerted will not make a tight fit unless we distort *A* or drive a wedge at *C*. This is analogous to a perfect thread, and driving the wedge at *C* is equivalent to introducing a slight difference in lead. If, now, we cut off the ends of *A* as shown in Fig. 3, and apply a force in the direction shown, we can obtain a forced fit because only the angles are complements and because we have a method of maintaining pressure. We can also even distort *A* because we have room for it to expand. We have only then to provide for three things: a method of making the parts in contact absolutely complementary; the introduction of sufficient metal; and a method of maintaining pressure. With our present type of thread we can only meet one of these—namely, that of partly maintaining

<sup>1</sup> Consulting Mechanical Engineer, Research Engineering Co., Mem. Am. Soc. M. E.

Abstract of a paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

pressure. This is demonstrated in Fig. 4, which shows in an exaggerated manner the effect of off lead.

While two slightly varying leads make a better fit, both as regards gaging and in actual use, this practice is not to be commended. Using a different lead to secure a fit is doing imperfectly on one side of the thread what the different-angle method does perfectly on both sides, because by having the leads identical and the thread supported on both sides, we secure a uniform finish instead of a distortion. Where the leads are different, the amount of distortion necessary to secure a fit increases with each thread. Thus, if the lead of a 20-thread stud is 0.05 in. and we make it 0.052 in., it will be 0.002 in. off center on the second thread and 0.018 in. on the tenth thread. This is entirely possible, and superior to a so-called perfect thread as regards fit, but a distortion, unmechanical, and unnecessary.

FIG. 4 THE EFFECT OF LEAD (GREATLY EXAGGERATED)

This is what is done with railroad fish-plate bolts where the specifications state the minimum foot-pounds at which the nut and bolt may be assembled. The impossibility of meeting these requirements in quantity production is recognized by purchasing agents and most engineers, and so the lead is slightly changed. This, however, is merely a subterfuge and really defeats the purpose of the specifications in that it permits of a poorer and weaker thread than would otherwise be possible.

We are thus confronted with this problem: Without sacrifice of strength, without increase of rejection, without additional manufacturing costs, find a method whereby a male and female thread of the same lead and pitch diameter may be made after repeated loosenings to fit tight without the aid of a locking device. This, according to specifications, calls for a full thread at contact points, pressure applied continuously on all flanks, and maximum strength at the pitch line. This means the addition of surplus metal to the male (which is the only one affected) sufficient to fill out the female threads, which would be an impossibility were it not for the ductility and elasticity of steel. If we add this surplus metal we will find that we can more than fulfill the required conditions by changing the angle of the male thread to a lesser one than that of the female, having the two intersect on the pitch line.

When a male thread of this type and a standard mate are screwed together, we will have transformed a male of lesser angle to one of larger angle or of wider base than the standard

U. S. thread, because we have filled out the female thread tolerance as well as that of the male. We will also have uniform pressure on all flanks; the maximum possible material at the pitch line; a hard, smooth surface analogous to a case-hardened one; a fit that will remain snug despite repeated removals and that may be screwed together by ordinary means; and yet we still retain an interchangeable bolt and nut according to U. S. standards. The nut has not been changed or distorted in any way, but has simply served as a finishing roll.

The writer has stated in a previous article that, aside from threads, nowhere else in machine work do we expect micrometer limits on a roughing cut; and the question naturally arises whether an operation similar to that described would not be an effective finishing and sizing operation for commercial work. This would be the equivalent of making them fit the gage, and

FIG. 5 DIFFERENT-ANGLE THREADS (GREATLY EXAGGERATED)

would greatly reduce the cost due to rejections. We would, of course, still have variable nuts and the necessity of sizing them.

#### REASONS FOR DEPARTING FROM ACCEPTED PRACTICE

Let us now see what authority and precedent we have for making so radical a departure from accepted practice. To do so, let us consider how threads are made, especially by rolling. Generally speaking, thread rolling is circular knurling, knurling being that process whereby the diameter of a part is increased at certain points by a corresponding reduction of diameter at other points, due to pressure alone. It is applicable to both flat and round surfaces, but for the purpose of this article we will consider only round surfaces.

In turning screws and bolts to size the diameter is held, generally speaking, to the pitch diameter. The displacement of metal from the root and lower flank forms the addendum under the process. Cutting a thread on a bolt with a die is a somewhat analogous operation, the similarity increasing as the die becomes duller. For a die-cut 1-in. bolt it will generally be found that with a diameter of 0.990 in. a fuller thread may be secured than with one of 1.000 in., the explanation being that with the die we secure a combined cutting and rolling operation. Due to lack of clearance, if the diameter is too large, part of the metal is pressed into the bottom of the die and with such force that it drags and is torn off, thus leaving a thread of smaller

outside diameter than would have been otherwise secured. This same phenomenon occurs when a nut is too tight.

If we require a holding fit on a shaft, do we use tolerances that allow of the shaft being several thousandths smaller than the hole it is to fit? Quite the contrary. We not only specify the fit but also the minimum pressure allowable to assemble the two parts, and we do this both for single units and for quantity production. We might term a shaft and rotor spider a nut and bolt with microscopic threads and assembled with a right-angled instead of a helical motion. Why not fit our bolts the same way, making our tolerances plus instead of minus and using a force fit we can depend upon when it means no change in the tools for assembly?

If we look at a finished commercial thread through a microscope, it will be seen that the edge is serrated and that slivers stand up all over its surface. By running a nut over it once we but slightly change its appearance, but by repeatedly doing so—always using a tight nut—we may finally burnish the thread so that it will not thereafter change its size and will have a surface somewhat comparable to a case-hardened one.

Fig. 5 shows diagrammatically the different-angle thread with the angles of the male greatly exaggerated to demonstrate the principle. We are complying in this case with all the conditions we have just been discussing: We are making the lesser contain the greater, angularly speaking; we are applying force from both directions, at right angles to the axis of the bolt; we have made the angles complementary—not merely two equal angles; we are securing the maximum strength at and near the pitch line, and transforming a thread with a lesser angle than that of the standard male to one with a larger angle, thus filling out the space perfectly and so doing away largely with vibration; and we are securing, whether under pressure or not, contact on all flanks, whereas the standard thread when under pressure secures contact on possibly one-half the flanks, both because it is compressible and because it does not fill the female thread. The only problem to be solved, therefore, was to find an angle of such slope that it could be formed without distortion of the nut or requiring too much force to screw home. To demonstrate this, threads as small as No. 10-32 were used, and as being of possible interest, the writer presents a brief outline of the engineers' report of the experimental work.

#### RESULTS OF EXPERIMENTAL WORK

Diagrams of the different threads were first laid out on a 100 to 1 scale so as to determine approximately the most suitable angles to be tested; the Löwenherz thread with an angle of 53 deg. 8 min. being used as a basis. The nut was to have the regular Löwenherz thread with same diameter and pitch as in the 155-mm. shell adapter used by the U. S. Government.

Threads of 44 deg. and 45 deg. for the plugs seemed most favorable and accordingly the following cold-rolled steel plugs were made up, with nuts having the same pitch diameter and lead as the plugs but a thread angle of 53 deg. 8 min.:

- 1 Angle of thread 44 deg. 54 min., pitch diam. 0.8748, lead 0.0787
- 2 Angle of thread 45 deg. 2 min., pitch diam. 0.8748, lead 0.0787
- 3 Angle of thread 44 deg. 0 min., pitch diam. 0.8748, lead 0.0787

**Test No. 1.** Nut No. 1 and plug with thread angle of 44 deg. 54 min. were screwed together *without* a lubricant. They were started about a half a thread by hand, and then an 8-in. wrench was used for about four threads. The plug was then so tight in that a 10-in. wrench was required to turn it to full depth. After a couple of backward turns the plug stuck so tight that a 20-in. wrench would not move it. The nut was then sawed open and removed from the plug and about one-third of a thread of the plug was taken off in a piece of the nut. A magnifying glass showed that the threads in both plug and nut were drawn and cut out of shape where there was a tendency for them to overlap, due apparently to too much metal and no lubricant.

**Test No. 2.** Nut No. 2 and plug with thread angle of 45 deg. 2 min. were screwed together *with* a lubricant. They were started by hand for about one-half turn, then an 8-in. wrench was used for five or six threads, and a 10-in. wrench for the remainder. The plug came out slightly easier than going in. After this had

been repeated three times the plug could be screwed in by hand. The maximum and minimum plug gage for the nut showed no change in the thread of the nut. Under a magnifying glass it was seen that the metal had flowed to the top of the plug thread from about the pitch diameter outward. The plugs were screwed into the nuts fifty times and there was still what could be termed a "snug fit."

**Test No. 7.** Plugs were tried out with commercial 1-in. nuts. The thread angle of the plugs was 58 deg., and the pitch diameter 0.9228 in., with one plug this diameter plus 0.001 in., and one minus 0.001 in. This diameter allowed the plug thread in the layout to overlap the entire thread of the nut instead of only half, as in the previous cases. The nuts used were picked out of stock for size with a standard 1-in. thread gage. The smallest plug went into the nut easily by hand. The largest two went together easily with an 8-in. wrench. After being twice screwed together with the wrench they went together with a snug fit by hand. The magnifying glass showed that the thread from near the pitch diameter outward had been drawn and compressed slightly.

**Test No. 9.** Plugs of  $\frac{1}{2}$ -in. diameter with pitch diameters of 0.4684 in. and 0.4699 in. (same as  $\frac{1}{2}$  S. A. E. nuts) and a thread angle of 50 deg. were tried with commercial  $\frac{1}{2}$ -in. S. A. E. nuts. The difference in the two pitch diameters made practically no difference in the fits, as they both readily went in with an 8-in. wrench. After they had been screwed together four times, they would go together by hand, but without shake. After they had been screwed together 75 times there was still what could be termed a "snug fit."

**Test No. 10.** An attempt was made to compare the strength of an S. A. E. standard  $\frac{1}{2}$ -in. thread with a 50-deg. thread of the same size. The plug with the standard thread on one end and the special thread on the other end was used with standard nuts. A pull of 14,000 lb. was gradually applied and the metal began to give way, which prevented an additional load. During this pull, observations were made to determine if there was any "give" in either of the threads, but both remained the same throughout. The nuts were removed and there was no apparent distortion of the threads.

**Test No. 12.** In this test  $\frac{1}{4}$ -20 plugs with pitch diameters of 0.2165 in. and 0.2181 in. with 50-deg. angle were tried out with  $\frac{1}{4}$ -in. U. S. standard nuts, one being a commercial nut and the other of a standard size but made in our toolroom—the tap being 0.250 in. in diameter. Both nuts were tried with a  $\frac{1}{4}$ -in. standard plug gage, both being apparently the same size. The nut made in the toolroom was screwed on the maximum plug and went on about one and a half times its length and then stuck and would not go either way. It was finally removed by hammering it on the sides. The threads were rolled and torn from about the pitch diameter outward, but there was not that tendency for the metal to roll upon the outside of the thread as in the previous tests, the outside diameter being only 0.251 in. as against its original 0.250 in.

The commercial nut went on the minimum plug with an extremely tight fit, but it came off very readily with the wrench and left quite a different thread from the previous one. The thread was not torn at all but rolled out to almost a perfect V-thread with outside diameters of 0.2555 in. as against the original 0.250 in. The outside diameter of the tap for the commercial nut must have been over 0.250 in. to allow this metal to flow out to 0.2555 in. and not jam the nut. If the toolroom tap had been sharper on the flats or its outside diameter greater, there would have been room for the metal in the test plug to flow out to a larger diameter and avoid tearing the thread, and consequent jamming of the nut. Two facts are clearly demonstrated: first, necessity of room for metal to flow; second, one of the limitations of the thread gage.

**Test No. 13.** Plugs corresponding to standard 10-32 with 50-deg. angle were tried out with standard 10-32 nuts; pitch diameters 0.170 in. and 0.1716 in. They were a little too tight a fit to go together by hand, but after being screwed together once with a wrench they went together by hand snugly.

# Pulverized Coal in Metallurgical Furnaces at High Altitudes

By OTIS L. MCINTYRE,<sup>1</sup> NEW YORK, N. Y.

The following paper describes experiments with pulverized coal which led to the installation of apparatus for its use in the blast furnaces, reverberatories, and sintering machines of the Cerro de Pasco Copper Corporation at La Fundicion, Peru. Information is given of the method of determining the firing performance of pulverized coal; the behavior of the various mixtures; experiences with different air pressures; and the effects of ash. The experiments were conducted at an elevation of 14,000 ft. and this fact greatly adds to the value of the data presented, for heretofore but little attention has been paid to the effects of altitude upon the burning of pulverized coal.

THE Cerro de Pasco Copper Corporation at La Fundicion, Peru, uses about 65,000 tons of coke per year, of which about 85 per cent is local coke made at the smelter, and 15 per cent is imported. This latter is very expensive, and of course both classes of coke enter largely into the smelting costs; consequently, about two years ago it was decided to determine what could be done in the way of using pulverized coal in the

mill, the product being stored in barrels until a sufficient quantity had been pulverized to run a test. An average screen test of this pulverized coal was about as follows:

+ 60 mesh	8.00 per cent
+ 100 mesh	8.00 per cent
+ 200 mesh	14.00 per cent
- 200 mesh	70.00 per cent

The equipment used in the test is shown by Fig. 1-A and consists of coal hopper, a 3-in. feed screw driven by variable-speed motor, and a No. 2 Sturtevant blower supplying the air. The burner was a standard 6-in. pipe projecting about 12 in. into the furnace, which was approximately 4 ft. by 4 ft. by 16 ft. and constructed of firebrick. A number of tests were run with this equipment and though no pyrometric measurements were taken, observation of the furnace showed the results to be satisfactory.

The tests were first made with pure pulverized coal, and then with mixtures of coal and coke breeze, varying from 10 to 35 per cent of coke breeze, which gave practically the same results as the pure coal. The layout was then changed, Fig. 1-B, to test the practicability of using more than one burner with a single feeder. This test was run with the 4-in. return pipe both open and closed, the results indicating that satisfactory operation could be obtained by either method with a properly proportioned pipe system.

The next test made was in the sintering of fine ores on a standard Dwight-Lloyd sintering machine. These machines are oil-fired, and if coal could be substituted it would show a considerable saving. The equipment used in this test was the same as was shown in Fig. 1, except that a 1-in. screw feeder, a smaller fan, and a 2-in. pipe burner were used. This test produced a satisfactory sinter, though some trouble was encountered

FIG. 1 LAYOUTS OF EQUIPMENT USED IN FURNACE TESTS OF PULVERIZED COAL

FIG. 2 LAYOUT USED TO TEST FEASIBILITY OF CONVEYING PULVERIZED COAL UNDER DIRECT AIR PRESSURE

various departments of the smelter. The preliminary work consisted in determining the general combustibility of the local coals in pulverized form. These coals are obtained from two mines operated by the company and have the following general analysis:

Ash	Volatile Material	Fixed Carbon
26.8	40.05	33.15

This coal was dried by hand on steam hot pans to less than 1 per cent moisture, and then ground in a 4-in. by 4-in. Marey

in the primary ignition of the coal, and the standard oil muffle proved to be too small.

The next experiment was to test the feasibility of conveying pulverized coal under direct air pressure. The layout used is shown in Fig. 2. Pulverized coal was placed in the pressure tank and air at 20 to 25 lb. was then admitted through the 3/4-in. pipe at the top of the tank. The 4-in. valve at the bottom was then opened and the coal passed through the 4-in. piping system to the coal hopper. In this way 4000 lb. of coal was transported in 1 1/2 to 2 min. The loss through the vent pipe varied from 100 to 200 lb. This can be taken care of by using dust collectors on the hopper, or an exhaust system which would return this waste coal to the main hopper.

For presentation at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

<sup>1</sup> Mech. Supt., Cerro de Pasco Copper Corp. Mem. Am. Soc. M. E.

The foregoing tests showing up so well, it was decided to erect a larger experimental pulverizing plant. There were available for this purpose one set of 18-in. by 36-in. rolls, one 4-ft. by 4-ft. Marcy mill and two 6-ft. by 4-ft. Allis-Chalmers ball granulators. The drier consisted of five passes of 16-in. by 12-ft. screw conveyor, mounted in a brick housing on top of the reverberatory flue, and through which part of the flue gases were by-passed. The layout in plan is shown in Fig. 3.

After completing this plant it was decided to make the first experiment on the blast furnaces, so No. 5 blast furnace was selected for the purpose and was equipped on one side only, as shown by Fig. 4. The coal was ground at the experimental plant and transferred to the No. 5 furnace in a hopper ear, being weighed in transit. A number of tests varying from 8 to 12 hr. were run with this equipment. The furnace air pressure averaged 34 oz., and auxiliary air for injecting coal about 22 lb. The coke charge was reduced first 25 per cent, and then 50 per

shifters. By using dust-proof bearings and a better-designed injector, we expect to eliminate this trouble.

Keeping the tuyeres open is absolutely essential to the safe and efficient operation of this process, and as it is a manual operation it must be handled by the operators. During these tests, tuyeres were "punched" every fifteen to twenty minutes on signal. On one occasion a tuyere became badly blocked, the feed was cut off and the tuyere cap opened. The blast from the furnace blew out a dense cloud of coal dust and molten material. The dust was ignited and burned on the outside of the furnace for 20 to 30 sec. with an intense flame about six feet long, the tuyere acting as an ordinary coal burner.

In view of the difficulty of keeping the tuyeres open and the connections airtight, it is probable that the most satisfactory place to inject the coal into the furnace would be through a separate opening in the jackets, between and preferably somewhat above the tuyeres.

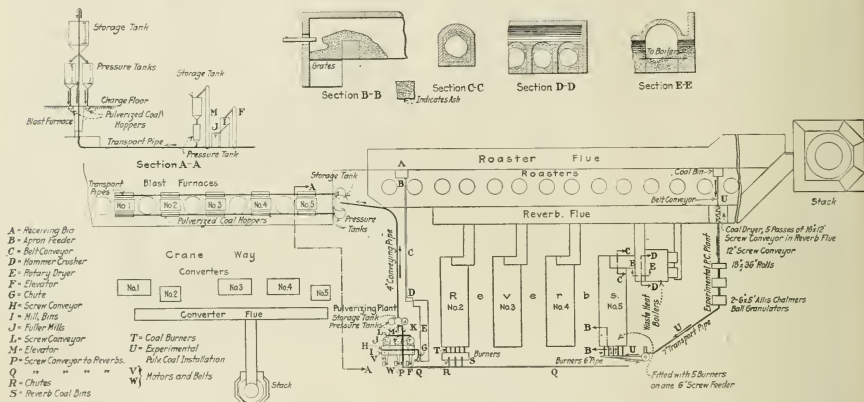

FIG. 3. LAYOUT OF PRESENT CERRO DE PASCO COPPER CORPORATION'S SMELTER, SHOWING LOCATION OF COAL-PULVERIZING PLANT

cent. These tests showed up so well that it was decided to equip the other side of the furnace with coal feeders and run a test of several days' duration. This was done and the results were entirely satisfactory. During these tests the auxiliary air was taken from the converter air line, which varied from 12 to 16 lb. pressure.

The following quantities will give an idea of the proportion of coke and pulverized coal used:

	14-Hr. Run	50-Hr. Run
Normal charge of coke, lb.....	31,000	114,000
Actual charge of coke, lb.....	17,000	61,500
Pulverized coal fed to furnace, lb.....	8,900	41,000

The analysis and screen tests of the coal used were practically the same as noted above. The furnace performance through all tests was carefully observed and was found to be fully equal to that when operating on the normal coke charge. Two difficulties were encountered on the blast-furnace test, namely, keeping some of the feeders in operation and keeping the tuyeres open. It was observed that in some of the feeders there was a slight back pressure, due probably to partially blocked tuyeres. This did not affect materially the feeding, but forced some coal dust into the feeder bearings which mixed with the oil and finally bound the bearings so that it became necessary to shut down that particular feeder and clean the bearings. This was easily done without shutting down the other feeders, as the gears on the main shaft were mounted on feathers and provided with

The No. 5 reverberatory was selected for the final test. All four reverberatory furnaces in use are identical: they are old style, designed for hand-firing and about 18 ft. by 58 ft. inside the bridge wall. No. 5 was fitted up as shown at U, Fig. 3. The coal was discharged from the last mill into a hopper and dropped into a 7-in. pipe where it was picked up by an air jet and conveyed to the coal hopper, a distance of about 150 ft. and rise of about 30 ft.; the top of the hopper was constructed similar to a cyclone dust collector. From the hopper a 6-in. variable-speed screw feeder fed the coal into the suction side of a No. 9 Sturtevant Monogram blower; this in turn discharged the mixture of coal and air into the feed piping from which branched five 6-in. pipe burners into the furnace, the excess air and coal returning to the hopper.

This test was disappointing from the actual results, but when the following difficulties which were encountered are corrected, the furnace will, beyond question, show a much higher efficiency than the hand-fired furnace. First, the coal could not be dried sufficiently, the average moisture being in excess of 1.5 per cent. This introduced handling troubles. The plant would not grind sufficient coal to the required fineness, the average screen analysis being:

+ 65 mesh	22.8 per cent
- 65 mesh	8.5 per cent
- 100 mesh	25.6 per cent
- 200 mesh	42.4 per cent

The discharge from hopper to feeder was too small, and the coal continually caked and bridged. The screw feeder was too short so that the coal flushed badly at times; also the discharge from the feeder was too far from the fan so that the coal accumulated in the suction pipe and had to be removed with an air jet. Under these conditions it was obvious that uniform feeding, which is essential to efficient operation, was impossible.

This test covered about nine days, and was run for about two days with the return pipe open. Sometime during the second day the return pipe was blocked, due to overfeeding, and it was decided to continue the test without opening the run pipe, the only difference being an apparently heavier feed at the burner farthest from the fan. With a properly designed piping system, there seems to be no reason why a series of burners cannot be operated from a single feeder with or without a return. The last day's run of this test was made with a mixture of 75 per cent coal and 25 per cent coke breeze, which gave results equal to straight coal.

The following table shows a comparison between the average performance of reverberatories Nos. 2, 3, 4 and 5 over the same period:

No.	Charge Smelted Per Hr.	Coal Used per Hr.	Smelting Ratio	Hr. Run	Time Lost
Aver. of 2-3-4	5.35	2.00	2.67	262	....
5	4.63	1.99	2.33	225	37

These results are really not so bad when the troubles encountered are considered and it is remembered that this furnace was not designed for pulverized coal and that it cools very rapidly during any shutdown, and considerable time is required to bring it up to the smelting temperature again.

As ash accumulations are an important factor in reverberatory smelting with pulverized coal, close observation was made of these accumulations, and the following samples taken:

1 Ash and slag float on the bath: comes out when skimming in small and large pieces, sometimes has to be broken to pass the skimming door, is easily handled when furnace is hot, but is tough and sticky when furnace is cool.

2 Ash in boiler cross-flue: Spongy mass of ash and some slag accumulates in fairly large quantities in cross-flue between furnace and waste-heat boilers; is soft and easy to remove when first deposited, but if allowed to remain, is very difficult to remove. (See sections E-E and D-D, Fig. 3.)

3 Ash on sides of roof of furnace: Almost pure ash, lightweight and brittle when cold, appears to accumulate on sides and roof of furnace until too heavy to stick, when it drops and floats on the bath.

4 Ash in reverberatory flue, very similar to No. 2 (See Section C-C, Fig. 3.)

Section B-B, Fig. 3, is taken at right angles to the bridge wall of the furnace and shows the large mass of ash, slag, unburned coal and coke which accumulated here and materially affected the operation of the furnace. This was deposited on the bridge wall and gradually built up in the shape of large horns in front of each burner, sometimes reaching within 8 or 12 in. of the burner.

Quite a large quantity of ash was deposited each shift on the boiler tubes, but was easily blown off by compressed air once or twice a shift. It was estimated that at least 50 per cent of the total ash was disposed of in the manner described, while the remainder was deposited in the main flue and went up the stack. The average ash analysis was as follows:

Si O <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	FeO	CaO	MgO	Cu
49.9	28.4	11.0	2.5	0.26	1.24

The high copper content is probably due to calceines lodging on the ash and slag float. Two samples showed Cu 2.92 and 1.91, respectively.

As a result of these experiments a modern 250-ton coal-pul-

verizing plant was designed and is now in course of erection. Blast furnaces, reverberatories and sinter plant will be equipped for pulverized coal, and the experiments will be continued to ascertain the equipment most suitable for local conditions, which will then be used at the new smelter now being constructed.

FIG. 4 EXPERIMENTAL PULVERIZED-COAL EQUIPMENT OF NO. 5 BLAST FURNACE

Fig. 3 shows the layout of the present smelter in plan, with various elevations, flow sheet of coal-pulverizing plant, and the location of this plant relative to the general smelter layout.

In conclusion, it may be of interest to note that these experiments and tests were carried out at an elevation of 14,200 ft.

The Historical Report of the Chief Engineer, Including All Operations of the Engineer Department, American Expeditionary Forces, 1917-1919, published by the War Department, consists of a main body and appendices. The main body constitutes the history of the engineers in France and is divided into three parts as follows: Part One deals with the organization and development of the department from the time of the appointment of the first chief engineer, A. E. F., May 18, 1917; Part Two is devoted to military engineering, including staff and army operations; Part Three relates to engineer activities in the services of supply, construction and forestry. The appendices consist of technical discussion, departmental and special service reports, regimental histories, and material of a similar detailed character.

# The Great Hydroelectric Plant at Keokuk

Excursion to This Plant Is Planned for Members and Guests of The American Society of Mechanical Engineers in Connection with Their Spring Meeting

THE Mississippi River Power Company's power plant at Keokuk, Iowa, is by far the greatest low-head hydroelectric development ever undertaken. The entire structure is built of monolithic concrete and includes a dam, powerhouse, navigation lock, and dry dock. Measured from end to end it is 10,560 ft., or two miles long, and is believed to be the largest monolith of its kind in the world.

It is located at the foot of the Des Moines Rapids, which extend from Montrose to Keokuk, a distance of twelve miles. In this distance the river bed has a fall of 23 ft., and the surface fall varies from 23 ft. at low water to 16 ft. at high water, which provides a normal working head for hydraulic machinery of

will provide room for 30 units each comprising a 10,000-hp. single-runner vertical Francis turbine connected to a vertical 9000-kva., 11,000-volt, 25-cycle, three-phase generator operated at 577 r.p.m. The present structure is only half of that called for by the plans, and provides for only 15 main generating units. For the substructure foundations, excavation was carried 25 ft. below the surface of the blue limestone bed of the river. From the forebay the water passes through the gate openings in the gatehouse section of the building, thence entering four branch intake tubes for each 10,000-hp. turbine. These four entry openings, 22 ft. by 7.5 ft., deliver the water to the scroll chamber at the sides and rear of the turbine setting. By the design of

GENERAL VIEW OF THE GREAT HYDROELECTRIC PLANT AT KEOKUK

32 ft., varying from 21 ft. to 39 ft. according to the stage of the river. The discharge of the river, at the site of the power station, where it is approximately a mile wide, is 200,000 cu. ft. per sec. at low water and 372,500 cu. ft. per sec. at the flood stage, which discharge made possible the project.

A 4650-ft. spillway dam of the gravity section type, which is surmounted by a bridge, extends from Hamilton, Ill., on the east side of the river, to the power house which is near the west side of the river. It consists of 119 arched spans, each having 30-ft. openings and 6-ft. piers. Each of these 30-ft. spillways may be closed by a gate or weir; in other words there are 3570 ft. of spillway. The upstream side of the spillway section is vertical; the downstream side is rounded off into an ogce curve which discharges the flow quickly into the river below.

In order that drift and ice may be excluded from the forebay, a 2340-ft. fender pier was constructed which extends upstream from the power house and curves toward the west shore. There is a 300-ft. opening between the shore abutment and the end of the pier to allow the passage of river traffic. When navigation is closed, or when there is a large amount of floating matter in the river, this opening is closed by means of a floating boom.

The completed powerhouse will be 1700 ft. by 123 ft. and

These figures are the results obtained by 20 years of observation.

the scroll chamber, 39 ft. in diameter and molded in concrete to follow the mathematical curvature required, the water is impinged upon the turbine blades from all sides with equal force and velocity. The draft tubes, 18 ft. in diameter at the rotor, enlarge rapidly as they assume a horizontal direction to empty into the tail race. Because of this design the water, as it enters, moves at a speed of 14 ft. per sec. and is discharged into the tail pool at about 4 ft. per sec.

A short dam, extending downstream from the power house, a navigation lock, and a dry dock at the west shore, form the forebay of the power house. The lock is a single 40-ft. lift, the chamber of which is 400 ft. by 110 ft., and may be filled in 10 minutes and emptied in 12 minutes. One of the features of this lock is the upstream gate, which may be described as a single leaf with a void chamber. This gate is operated as follows: To open it, the chamber is filled with compressed air, and because of the buoyant effect it floats into place; to close it, the compressed air is allowed to escape, and it sinks into the chamber provided for it because of its weight.

At the present time this station provides 110,000 hp. to St. Louis, East St. Louis, Alton, Hannibal, Quincy, Burlington, Ft. Madison, and adjacent territory; hence, it serves a population of about 1,120,000. With the 15 generators at the station it is possible to develop 13,500 kva.

# The Dissipation of Heat by Various Surfaces

By T. S. TAYLOR,<sup>1</sup> PITTSBURGH, PA.

Although it has long been the popular opinion that by covering hot-air pipes with sheet asbestos the heat loss was thereby reduced, some recent experiments by the author of the following paper indicate that quite the opposite is the case. Using bare tin as a standard of reference, he found that tin covered with 0.33 mm. (0.013 in.) of sheet asbestos will dissipate about 37 per cent more heat; asbestos-covered tin having a layer of dust, 32 per cent more; and tin with a layer of dust only, 7 per cent more. Calculations based on a series of tests indicate that it would require a covering of about 0.2 in. of sheet asbestos to make the loss from the covered pipe equal to that from the bright uncovered pipe. A thickness of 0.4 in. of asbestos, however, would result in a saving of 25 per cent over that of bare pipe, and about seven layers of 0.013 in. sheet asbestos loosely applied on a bare pipe would effect a saving of about 75 per cent. The author also presents figures, derived from tests, showing the effect of air velocity upon the dissipation of heat. Curves are given showing the watts dissipated per unit area and air velocity for definite surface temperature excesses of from 10 to 70 deg. The effect of the angle of incidence of the air is also discussed in the light of experimental work and it is shown that the maximum dissipation of heat takes place when air is blown over the object at an angle of from 40 to 45 deg.

NOT long ago, while conducting a series of tests to determine the relative thermal insulating properties of asbestos, it was observed that warm water placed in a plain tin vessel cooled more slowly than when placed in a similar vessel covered with thin sheet asbestos. Since this observation was in direct contradiction to popular opinion, it seemed worth while to make some definite tests on the relative dissipation of heat by such surfaces in still air. To conduct such tests tin vessels were accordingly constructed with a lid at one end and having a diameter of 10 cm. and length of 50 cm. A cylindrical heater was made by winding No. 21 constantan wire longitudinally on an asbestos-board framework so as to slip readily into the vessels. The heater was so constructed that the same amount of heat would be developed per unit area of surface of the vessels, both sides and ends. This made it possible to maintain the temperature within the vessel at various values above the surrounding air temperature.

The outer surfaces of the vessels were as follows: plain bright tin; tin covered tightly with 0.33-mm. (0.013 in.) sheet asbestos; tin covered loosely with three layers of 0.33-mm. asbestos; tin aluminum-painted; galvanized; and various dust-covered surfaces. A thermometer inserted through the side of each vessel provided means for measuring the temperature at the center of the vessel, and thermocouples of 0.005-in. copper-constantan wire were attached to the outer surface of each vessel so as to measure their surface temperatures. The vessels were always placed horizontally in such positions in the room as to be free from unnecessary convection currents.

Observations were taken of the amounts of electrical energy, measured by ammeter and voltmeter, necessary to maintain various differences between the temperature within the vessel as determined by the thermometer and the surrounding temperature. Surface and room temperatures were also taken at the same time.

<sup>1</sup> Mellon Institute, University of Pittsburgh; formerly of the Westinghouse Electric & Manufacturing Company.

<sup>2</sup> Since compiling these results the writer has learned that somewhat similar results have been observed independently by V. S. Day at the University of Illinois and were noted at the meeting of the National Warm-Air Heating and Ventilating Association, Columbus, Ohio, June 11, 1919. Observations showing the results outlined in the earlier portions of the present paper were first taken about February 1, 1919. Nothing further was done at that time owing to the pressure of other work. Recently, however, occasion permitted further work and the results confirmed the original ones. A preliminary notice of the present results appeared in MECHANICAL ENGINEERING for January, 1920, p. 69.

Abstract of a paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

The room temperature was taken at points sufficiently distant from the vessel to be uninfluenced by it. In this manner results were obtained showing the watts dissipated per unit area for various temperature excesses, internal above room, for different surfaces. Curves 1 and 2 in Fig. 1 show the results obtained for tin covered tightly with 0.33-mm. sheet asbestos and bare tin, respectively. Curves 1' and 2' give the relations in watts per sq. cm. per deg. cent. plotted against temperature for the corresponding surfaces. It is seen that the dissipation of heat per unit area per degree of temperature excess increases almost uniformly with the temperature difference over the range of temperatures used. Thus the curves 1 and 2 can be represented approximately by the relation,  $W = AT + BT^2$ ; where  $W$  is the watts dissipated per unit area,  $T$  the temperature excess (internal above surrounding air) and  $A$  and  $B$  constants for each surface.

Table 1 gives the values of the heat dissipated by the various

FIG. 1 HEAT DISSIPATED FROM TIN TIGHTLY COVERED WITH 0.33-MM. SHEET ASBESTOS

surfaces at corresponding temperature excesses. In addition to the surfaces listed in Table 1, results were also obtained for galvanized surface and tin loosely covered with three layers of sheet asbestos when dust-covered. Table 2 gives the relative

amounts of heat dissipated as compared with bare tin for corresponding differences in temperature. Tin covered tightly with one layer of 0.33-mm. sheet asbestos will dissipate 37 per cent more heat in still air than the bare tin. Even when both are covered with dust, such as that usually found on furnace pipes, the asbestos-covered surface will lose 23 per cent more heat than the bare one. The effect of dust on the pipes is to increase the loss of the bare pipe and decrease the loss of the asbestos-covered one. It requires at least three layers of 0.33-mm. sheet asbestos applied loosely on a bare pipe in order to dissipate no more heat than the uncovered bare pipe. This is readily shown by Table 2.

It will be observed from a study of Table 2 that the ratio for

all surfaces with respect to the bare pipe becomes somewhat smaller with increasing temperature excess. This indicates that if the temperature difference were high enough, very little difference would exist between the amounts of heat dissipated by each. This condition would not exist, however, until the surface temperatures were such that the heat would be lost chiefly through radiation, which for the present temperature range plays but little part.

#### HEAT LOSSES FROM HOT-AIR PIPES

One very interesting feature about these results is their application to the loss of heat by hot-air furnace pipes. From the results in Tables 1 and 2 it is quite evident that hot-air-furnace pipes lose more heat when coated with the usual sheet asbestos than when left bare. Furthermore, this difference is too great to be merely given a casual consideration, and the following brief discussion will emphasize the point. Let us consider in the first place what thickness of covering would be necessary in order to insure no more loss of heat by the covered pipe than by the uncovered one. For the same temperature excess, say, 40 deg. cent. internal above surrounding air, the covered pipe loses  $17.52 \times 10^{-3}$  watts per sq. cm. while the bare pipe loses  $12.70 \times 10^{-3}$ . This is seen by reference to curves 1 and 2 in Fig. 1. Experiments show that a covered pipe (No. 1) to lose only  $12.70 \times 10^{-3}$  watts per sq. cm. would require an outer-surface temperature excess of 12.8 deg. cent., and that when losing  $17.52 \times 10^{-3}$  watts per sq. cm. its surface temperature excess is 17.2 deg. cent. Hence sufficient insulation must be added to reduce the surface temperature to the lower value, or there must be enough asbestos added to produce a drop of 4.4 deg. (17.2—12.8). The thickness of asbestos necessary is given by the following equation:

$$12.7 \times 10^{-3} \times 0.239 = \frac{4.4 \times 0.00035}{d}$$

where 0.239 is the factor to reduce watts to calories and 0.00035 the thermal conductivity of asbestos paper in calories per cm. per sec. Solving the equation for  $d$  gives a value of 0.51 cm., which is practically 0.2 in. While this is an approximate solution it shows that considerably more thickness of insulation should be applied to hot-air pipes in order to make them as efficient as if they were left bare.

It is interesting to speculate as to the possible saving that would result by leaving the pipes bright and uncovered. Suppose there is a temperature excess, internal above surrounding air, of, say, 40 deg. cent. (72 deg. Fahr.). As is shown above this corresponds to a loss of  $17.52 \times 10^{-3}$  watts per sq. cm. or 0.113 watt per sq. in. from the covered pipe. If we have 10 pipes 10 ft. long and 10 in. in diameter, that is, approximately 36,000 sq. in. of surface, the total loss would be  $0.113 \times 36,000 = 4068$  watts. The total loss per day would be  $4068 \times 24 \times 3600$ , or  $3.52 \times 10^7$  joules. One pound of coal has a heating value of approximately 12,500 B.t.u. =  $1.32 \times 10^7$  joules. Consequently the loss in pounds of coal per day would be  $3.52 \times 10^7 \div 1.32 \times 10^7$ , or 26.6. This would be equivalent to about 75 bu. during the heating season. The loss through a bare pipe would be equivalent to  $100 \div 137$  (see Table 2) of this value, or about 54 bu. These considerations indicate, therefore, that the pipe system in question covered with 0.33-mm. sheet asbestos will lose during a winter season a quantity of heat equivalent to that obtained from 20 bu. of coal more than the same system would lose if left uncovered.

The explanation of the larger loss through a pipe when covered

FIG. 2 APPARATUS USED IN MEASURING HEAT LOSSES

with a thin layer of asbestos is due to the fact that the asbestos surface is some three or four times as great as the plain tin surface so far as molecular dimensions are concerned. The loss being due chiefly to air contact, it is readily seen that the greater the surface for the molecules to come into contact with, the more heat will thus be liberated. The radiating power of the asbestos also being larger than that of tin, will contribute an additional amount to the advantage of the asbestos as far as heat loss is concerned. The loss due to radiation, however, at these temperature differences is quite small compared with that lost by convection currents. Since the asbestos surface facilitates the loss of heat due to its increasing the effective molecular contacts, the surface of the asbestos and also the outer surface of the tin will thus have their temperatures considerably decreased and the result will be that more heat must pass through the tin and asbestos as a consequence of this condition. Therefore, when the surface of the pipe is thus changed and the heat losses increased for a given temperature gradient, it is necessary to overcome this by increasing the thickness of the asbestos layer to such an extent that the thermal resistance of the pipe and asbestos or insulation will cut down the heat flow to the desired amount. That is, the radiation resulting from increasing the effective area must be counteracted by increasing the thermal resistance through the addition of a greater thickness of insulation.

#### INFLUENCE OF AIR VELOCITY ON DISSIPATION OF HEAT

The work described under this heading was primarily undertaken for the purpose of securing data useful to engineers in

designing electrical apparatus. The results obtained are for the surface of a typical end coil of a turbo-generator, but they nevertheless are of value to anyone who is interested in the problem of air cooling. The apparatus upon which the wrapper, composed of treated cloth and tape, was placed was the same as had been previously used in measuring the thermal conductivities of coil wrappers (see *Electrical World*, February 14, 1920, p. 369). An iron bar  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. by 24 in. was used as a core in order to secure rigidity. A layer of  $\frac{1}{8}$ -in. heater mica was pressed over the core and a heater wire of No. 21 constantan wound over the mica so as to have eight turns to the inch. The

FIG. 3 EFFECT OF AIR VELOCITY ON DISSIPATION OF HEAT

space between the turns was filled with asbestos cement and a second layer of  $\frac{1}{8}$ -in. heater mica plate was then pressed over the entire apparatus. After having been thoroughly dried out by sending a current through the heater wire while the entire heater was held between clamps, the apparatus was wrapped with the insulation according to definite specifications. Two thermocouples were placed on the wrapper on each side of the heater, one at the center of each side and another at the edge at corresponding positions along heater. The thermocouple wires (0.005 in. copper and constantan) were run out along the heater its entire length, the copper ones to one end and the constantan to the other. A sketch of the heater is shown in Fig. 2.

The heater after having been thus wrapped and arranged was placed about eight inches in front of the outlet of a blower and parallel to the opening so that the air stream fell at right angles upon it. The ends of the heater were covered with wool felt to prevent loss of heat therefrom. The outlet from the blower was of such dimensions ( $2\frac{1}{4}$  in. by  $2\frac{1}{4}$  in. by 24 in.) that the coil was completely within the air stream. Baffle plates placed in the air channel made it possible to secure a symmetrical distribution of the air stream. A small pitot tube made from a hypodermic needle was used to measure the velocity. The differences of pressure were read on a differential draft gage. Observations were also made of the air temperature and barometric pressure. The velocity of the air ( $V$ ) was calculated for standard conditions, 760 mm. pressure and 25 deg. cent. temperature, by use of the formula

$$V = \sqrt{\frac{2ghd}{\alpha}}$$

where  $g$  is the acceleration due to gravity,  $h$  the height of the liquid in the differential gage,  $d$  the density of this liquid, and  $\alpha$  the density of the air.

Measurements of the air velocity at the point in the air stream where the coil was situated showed but little variation from that for corresponding points at the opening. At least, whatever variation did exist was of the same order of magnitude as the experimental error. It was therefore assumed that the average of the velocity would be a fair value to take as the velocity of the air blowing over the coil.

The current in the heater was maintained constant and a constant number of watts were thus dissipated per unit area. Observations were taken from the excess of the surface temperature of the coil (determined from the average of the eight thermocouples on its surface) above the temperature of the impinging air for various air velocities and it was found that the heat liberated per degree excess increases approximately uniformly with the velocity over the range of velocities investigated.

In the above manner relations were determined for various amounts of heat liberated up to 0.186 watt per sq. cm (1.2 watts per sq. in.). From these values relations were obtained between the watts dissipated per sq. cm. and the corresponding temperature excess of the surface above air temperature for various air velocities. The curves in Fig. 3 show the watts dissipated per sq. cm. and corresponding temperature excesses for air velocities of 0, 800, 1600, 2400, and 4000 ft. per min. For still air it is seen that the amount of heat liberated per degree of temperature excess increases with increasing temperature excess. On the contrary, it is seen that the watts liberated per unit area per degree excess is practically constant for all air velocities other than natural convection currents. The watts dissipated per unit area varies uniformly with the temperature excess for constant air velocities. However, it is not safe to assume from these

FIG. 4 EFFECT OF ANGLE OF INCIDENCE ON DISSIPATION OF HEAT

experiments that such linear relationships continue to hold indefinitely as the watts dissipated increases.

#### EFFECT OF ANGLE OF INCIDENCE OF AIR STREAM

All the foregoing results were obtained for perpendicular incidence or when the angle of incidence of the air stream was zero. From results that had been obtained previously on the cooling of a very small coil of wire ( $\frac{1}{8}$  in. in diameter) when placed in an air current, it was seen that the amount of heat dissipated for a given temperature excess was different for different angles of incidence of the air stream. It therefore seemed worth while to make some tests to determine the way in which the temperature excess of the surface of the coil wrapper varied with the angle of incidence for a definite amount of heat dissipated per unit area and constant air velocity. This was done for a dissipation of 0.145 watt per sq. cm. (0.938 watt per sq. in.) and an air velocity of 3267 ft. per min. Curve No. 1, Fig. 4, shows how the temperature excess changes under the above conditions as the angle of incidence of the air stream changes from 0, that is, perpendicularly, to 90 deg. or parallel to the coil. Curve No. 2 shows how the watts per sq. cm. deg. cent. changes with the angle of incidence. The curves are quite interesting in that they show the relative cooling effects of air at various angles of incidence. It is seen that the temperature excess for the particular air velocity of 3267 ft. per min. and a dissipation of 0.145 watt per sq. cm. at an angle of incidence of air stream of about 40 to 45 deg. is only 67 per cent of what it is for an angle of incidence

### Muffler Design; Back Pressure in Exhaust Line and Power Loss of Aeroplane Engines

INVESTIGATION OF MUFFLING PROBLEM FOR AEROPLANE ENGINES, G. B. Upton and V. R. Gage, Members Am.Soc.M.E. Data of tests carried out under the auspices of the National Advisory Committee for Aeronautics on a Curtiss aeroplane engine and several stationary and other engines, using a fan dynamometer.

The paper describes in considerable detail the methods of measurements and the formula used. As regards the relation between back pressure and power output, it appears to have been found that for moderate back pressures the power loss is substantially proportional to the back pressure, while for higher back pressures the power loss mounts rapidly, apparently at such a rate that a

FIG. 1 INDICATOR DIAGRAM SHOWING LOSS OF POWER THROUGH BACK PRESSURE AT EXHAUST VALVE

back pressure of even less than 10 lb. per sq. in. would stop the engine.

A possible explanation of this changing effect of back pressure as the back pressure increases may be found by considering the indicator card. This is schematically shown in Fig. 1. For small back pressures we may expect the main effect to be a lifting of the exhaust line of the card by an amount substantially equal to

the increase of back pressure. The result would be a loss of indicated mean effective pressure equal to the back pressure, because the elevation of the exhaust line would extend through the whole stroke. The loss of brake mean effective pressure will be smaller than the loss of indicated mean effective pressure in the ratio of the mechanical efficiency of the engine to unity.

At higher back pressures the exhaust gases are held back in greater amounts in the cylinder, leaving the clearance space, at the end of the exhaust period, filled with an abnormal weight of

FIG. 2 TANGENTIAL-WHIRL-CHAMBER TANK MUFFLER RECOMMENDED BY THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS FOR THE LIBERTY AEROPLANE ENGINE

hot, dead gases. These reexpanding, interfere with the incoming charge in various ways, lessening the amount of the fuel mixture drawn in. The decrease of charge quantity will result in a decrease of the mean effective pressure which is added to the decrease of mean effective pressure due to lifting of the pressure of the exhaust line.

Probably it is the decrease of charge which is the principal reason for the possibility of stalling the engine by fairly completely choking the exhaust pipe and before complete closure is reached.

It was also found, as regards the relation between the brake horsepower and the actual back pressure, that "the back pressure increases as some exponential function of the horsepower, when the conditions of the exhaust passages remain unchanged" [quoted literally.—EDITOR.].

Data are presented to demonstrate that the choking of the exhaust by sharp turns, pipe fittings, etc., gives the same results as choking by a muffler.

In the course of the experimental work carried out some peculiar phenomena were noted. One such was the abnormal power drop,

considering the back pressure, at certain critical speeds. It was found that this abnormal power loss could be avoided by a very small change of speed either way from the critical.

The critical speed changed or disappeared with change of exhaust manifold. The supposed cause of this abnormal power loss at the critical speed is a reflected wave of exhaust gas killing the clearance of some cylinder just before its exhaust valve closed.

A number of mufflers were tested.

The authors recommended a tentative design for the Liberty 12-cylinder engine, that shown in Fig. 2, where air is supposed to pass through the inner tube to some extent aiding in cooling. (*National Advisory Committee for Aeronautics*, Report No. 55, preprint from Fifth Annual Report 1919, 38 pp., 27 figs. and numerous tables, e)

### Blast Engine with Reaction Jet Propulsion

**MÉLOT SYSTEM OF AIRCRAFT PROPULSION.** At the recent Paris aeronautical show there was exhibited a trial machine embodying the Mélot principle of propulsion. It is stated that the inventor experimented during the war at the *Laboratoire du Conservatoire des Arts et Métiers* in coöperation with the French Ministry in Munitions.

The machine consists of a burner with fireproof lining. Into this an explosive mixture is injected and ignited in the first instance by a spark plug, after which combustion continues uninterruptedly. The burned gases are exhausted through a blast

FIG. 3 MÉLOT SYSTEM OF PROPULSION FOR AIRCRAFT

pipe and four blast "engines," which are really graduated nozzles, one large and three small.

At the inlet mouth of each of these nozzles air is drawn in by suction, and the whole mixture of air and burned gases is exhausted by the last and largest blast engine and makes a direct thrust against the air at the rear of the engine (Fig. 3).

The machine is said to give 30 hp. for a relative speed of 50 m. (164 ft.) per sec. The weight per horsepower is said to be 0.5 kg. (1.1 lb.), and it is obvious that if the machine is capable of functioning for any length of time, its cost ought to be quite low because of the absence of valves, pistons and other parts of the conventional engine. (*Aeronautics*, vol. 18, no. 331 (New Series), Feb. 19, 1920, p. 157, 2 figs., d)

**THE AERODYNAMIC PROPERTIES OF THICK AEROFOILS,** F. H. Norton. A report dealing with the results of a series of tests conducted at the Massachusetts Institute of Technology wind tunnel, with a view to developing aerofoil sections thick enough to permit of internal bracing and the use of cantilever wings without any external bracing of the airplane wing truss. The sections tested were based on the Durand 13, and were varied in section form, in thickness along the span, and in chord along the span. Tapering both in thickness and in chord was found to be highly beneficial to efficiency, and some of the wings developed have  $L/D$  ratios practically as high at angles corresponding to very high speeds of flight as the best of the wing sections for normal type, together with very much higher maximum lift coefficients. In particular, it was found that the substitution of a thick tapered wing for R. A. F. 6 on a 3600-lb. fighting biplane with Liberty engine would increase the maximum speed by 18 m.p.h., due to the saving in parasite resistance by entire elimination of the interplane bracing. Report No. 75 of the *National Advisory Committee for Aeronautics*, preprint from Fifth Annual Report 1920, pp. 5-26, 29 figs., te)

### BUREAU OF STANDARDS

**VAPOR PRESSURE OF AMMONIA,** C. S. Cragoe, C. H. Myers and C. S. Taylor. The previous measurements of the vapor pressure of ammonia are briefly reviewed and tabulated. A detailed description is given of the apparatus and method employed in the present measurements throughout the temperature interval  $-78$  deg. to  $+70$  deg. cent. Seven samples of thoroughly purified ammonia were used. Special tests showed less than one part in 100,000 by volume of non-condensing gases and less than 0.01 per cent by weight of other impurities. The methods of purification and filling manometers are briefly described. The phenomenon of hysteresis was observed near the normal boiling point of ammonia with a commercial sample containing a small amount of air, which indicated the necessity of very complete removal of dissolved gases for any accurate measurements of vapor pressure by the static method. Lags in coming to equilibrium were encountered and studied in order to determine the most advantageous procedure in establishing equilibrium. The normal boiling point of ammonia was determined by the static and also the dynamic method, the mean of the results by the two methods being  $-33.35$  deg. cent. Two empirical equations were found to represent closely the results in the temperature range covered experimentally and also the latest determination of the critical data for ammonia. The results of 122 measurements in the interval  $-78$  deg. to  $+25$  deg. cent. made with direct observations of mercury columns agree with the empirical equations within 1 mm. of mercury. The results of 28 measurements in the interval  $+15$  deg. to  $+70$  deg. cent. made with an accurately calibrated piston gage agree with the empirical equations within about 3 mm. of mercury. As a final result the vapor pressure of ammonia is expressed in the range  $-80$  deg. to  $+70$  deg. cent. by either of the following equations:

$$\log p = 30.256818 - (1914.95669/\delta) - 8.4598324 \log \delta \\ + 2.39309 \times 10^{-6} + 2.955214 \times 10^{-6} \delta \\ \log p = 12.465400 - (1648.6068/\delta) - 0.01638646\delta + 2.403267 \\ \times 10^{-6} - 1.168708 \times 10^{-6} \delta^2$$

where  $p$  is expressed in mm. of mercury and  $\delta$  in degrees absolute (deg. abs. = deg. cent. + 273.1). (*Abstract of Scientific Papers of the Bureau of Standards* No. 369, e)

### ENGINEERING MATERIALS

#### Does Pickling Affect the Quality and Machinability of Steel?

**EFFECT OF PICKLING ON ALLOY STEEL,** H. L. Hess, Mem. Am. Soc. M. E. Pickling is extensively used, as it facilitates the discovery of seams and surface defects generally, and removes all furnace and rolling scale. Various solutions are used, such as highly diluted baths of sulphuric or hydrochloric acids.

A series of tests were carried out by the metallurgical department of the Hess Steel Corporation, Baltimore, Md. In these tests 1 lb. of a special pickling compound (not otherwise specified) was dissolved in 3 gal. of water, and the mixture held at a constant temperature of about 200 deg. Fahr. The tests were made on round pieces ( $1\frac{1}{2}$  in. in diameter and 3 in. long) of chrome steel with approximately one per cent carbon and 1.50 per cent chromium.

As the object was to determine the lasting effect of the pickling on the metal, various subsequent treatments were used in order to neutralize fully or partly the effect of the pickling, the pieces being washed in cold, hot or lime water and tested either immediately or after periods varying from 7 to 28 days. The tests were made for hardness without cleaning, polishing or filing the surfaces in any way previous to the test, this being done in order to avoid the possible removal of a skin which might have appeared as a result of the pickling.

On the whole, it was found that the hardness results do not seem to be affected by the pickling treatment, although there was a slight indication that the unpickled steel has a somewhat softer surface than the pickled specimens.

Careful machining tests showed absolutely no difference in machinability, and it would appear that pickling affects only the skin, and even that to an effect not noticeable in machining.

Further tests were made to find out, if possible, whether pickling would have any effect upon the surface of the material and whether this effect were traceable to any appreciable depth. In these tests each piece of steel was subjected to a careful microscopic examination of the surface before and after aging and at various magnifications. The photomicrographs do not show any distinct difference between the pickled and unpickled bars.

The general conclusion drawn from these tests is that pickling in itself, as well as pickling followed by various treatments, does not interfere in any noticeable way with the quality or machinability of the steel. (*Iron Age*, vol. 105, no. 9, Feb. 26, 1920, pp. 593-594, 6 figs., e)

## FOUNDRY

### Howe Suspended Molding Machine

**SUSPENDED MOLDING MACHINE.** Description of the installation and use of suspended molding machines at the works of the Standard Malleable Iron Company, Muskegon Heights, Mich., where it is claimed that their use effected an increase of production per molder of from 15 to 30 per cent, depending on the class of work done.

The machine hangs on a rail which extends lengthwise over

the aisle to the wall parallel with the course of the molding machine. At the close of molding operations for the day, the sand machine cuts the sand in each pile in the foundry. It moves from aisle to wall and back in the brief space of  $1\frac{1}{2}$  min. as compared with 30 min. of hand labor employing several men.

Each of the molding benches is equipped with adjustable shelves and a long side bench, the latter being attached to the machine by a bracket and supported on a wheel. (*Iron Age*, vol. 105, no. 10, Mar. 4, 1920, pp. 665-666, 3 figs., d)

### Single-Sleeve-Valve Engine with Outside Sleeves

**MELTON-HAURY ENGINE.** Description of a new engine, known as the Melton-Haury, whose characteristic feature is the single sleeve located outside of the cylinder, which means that the usual amount of water-cooling area is available.

The single-sleeve valve (Fig. 5 on the following page) is a cylindrical structure with port openings of large area. This cylindrical structure is split longitudinally and must be sealed

FIG. 4 HOWE SUSPENDED MOLDING MACHINE WITH SQUEEZER ATTACHMENT

the milling floor and is easily movable from place to place. It is equipped with pneumatically controlled legs (Fig. 4) by which it can be held firmly in a stationary position regardless of the irregularities of the floor. These legs are in reality plungers fitted in pneumatic cylinders and are controlled by a stopcock.

In its simplest form the machine is really a movable molding bench. With benches fixed at the walls, the molder was forced to carry his work over the floor to the aisle, running the risk of shifting the molds. The suspended bench enables him to commence work close to the aisle near his sand pile and gradually move toward the wall as his day's work progresses. The machine also enables the molder to handle all his own molds, even such where ordinarily a helper would be needed to carry them out.

Another advantage of this device is that the molder's afternoon work is not interfered with by the heat radiating from the hot sand dumped from the morning molds.

It is claimed that the machine facilitates the use of a sand cutter. The sand is dumped from the flasks in a pile extending from

in that direction. This is accomplished by a dovetailed edge that effectively seals the joint.

The cylinders are removable and are machined inside in the same manner as poppet-valve engines, giving also a minimum of friction surface on the outside, the valves traveling against this outside surface with the bearing surface integral with the block.

The valves are positively operated by individual valve shafts driven by helical gears, these shafts being located directly below the driving lug on the sleeves in order to reduce any side thrust or undue strains.

The construction is of interest because it permits the cylinder to be well cooled while the sleeve valve is amply lubricated. On the exhaust side, the exhaust manifold is provided with hot points protruding downward into the intake manifold against which the carburetor is attached. The gases, being preheated, pass through the block between the cylinders into the distributing manifold inside of the engine block. (*Commercial Car Journal*, vol. 18, no. 6, Feb. 15, 1920, pp. 23-24, 3 figs., d)

### Design and Materials for Pots and Boxes Used in Carbonizing; Heat-Resisting Alloys; Q-Alloy of Nickel-Chromium Family

POTS AND BOXES USED IN CARBONIZING, H. H. Harris. While heat-treating furnaces and processes have been consistently developed in the last score of years the pots and boxes used in the cyanide and lead-hardening processes have changed very little.

Three factors govern the service received from carbonizing pots and boxes, namely, design, method of manufacture, and material. As regards design, the author states that while in some plants there have been considerable improvements, through the industry at large a great majority of carbonizing boxes are of a design as well adapted for packing soap in as they are for carbonizing, which affects the results obtained in a very undesirable manner.

To be good a box must be designed to permit tight sealing with some refractory or other material, in such a manner, however, that the clay should not enter the box and mix with the compound.

Proper dimensions of the box are also important. The thickness of the box should be as thin as possible in order to prevent warpage and still sufficient to permit proper flow of metal in the casting.

Materials for pot and box manufacture may be grouped into six classifications: cast iron, cast steel, pressed and rolled steel, "trick" materials, alloys and materials calorized.

Cast iron is both the cheapest first-cost material and the poorest. It oxidizes rapidly, gives a non-uniform service, becomes distorted easily, forms scale which mixes with the carbonizing

compound and is likely to spoil the work, and finally is affected by the cyaniding mixtures.

Cast steel is generally much superior to cast iron. It costs about twice as much per pound, but may give much longer service. The principal objection to cast steel is that the grade of steel used for pots and boxes is usually of inferior quality, sometimes even semi-steel being offered for steel. The method of casting the pots and boxes is also often unsatisfactory.

Judging, however, from the average of various types and conditions studied in many of the largest plants in the country, the author does not believe that any material has shown on the average a uniformly longer life per dollar invested than cast steel, with the exception of a nickel-chromium alloy which he refers to as "Q-alloy."

Pressed- and wrought-steel pots were quite generally used some time ago before the advance in price of this material. Its advantage is its light weight and consequent small heat consumption. Its disadvantages are its high price and the comparatively few shapes in which it can be secured. Some companies manufacture their own annealing boxes from wrought steel, riveting or welding them together. Some of these are said to give satisfaction in extreme temperatures, but not under general conditions. Wrought-steel riveted or welded pots for cyanide, chloride or lead conditions have never been successful owing to leakage.

By "trick" materials, the author means products misrepresented by their makers or sold under a trade name which does not correctly indicate their nature. Alloys for heat-resisting purposes are a new development and may be said to be still in their infancy. At this time there are more than 35 patents covering heat-resisting alloys.

The latest development in the alloy field is a special nickel-chromium alloy, the analysis of which the author is not yet authorized to divulge. This material differs from nickel-chromium alloys on the market in that it retains many of the physical characteristics of the cold metal at a temperature of 2800 deg. Fahr. and rings like a bell when struck with a hammer at this temperature. This new alloy is known as Q-alloy, grade X.

The only true scale of value by which a user can judge most competitive production materials consumed in service is by comparing their life under service conditions with their initial cost, and determining how many units of service each renders per dollar investment. In computing pot and box cost a unit is a heat-hour, which is an hour in the furnace under heat. Cost per heat-hour is arrived at by dividing the number of heat-hours received into the initial cost of the pot or box; for instance, if a cast-iron box weighing 100 lb. and cost 5 cents per lb. runs 100 heat-hours, the cost is 5 cents per hour. A steel box at 12 cents per lb. should run at least 300 hours under the same conditions, making a cost to the user of 4 cents per heat-hour. Under certain circumstances parallel to this Q-alloy has been known to run 7000 hours, making a cost to the user of 2 cents per heat-hour. Where an alloy affords a saving in cost per heat-hour it minimizes warpage and allows a thinner section to be used, thereby saving fuel in heating the box and its contents.

Thousands of tons of metal per annum are being consumed in the fires of heat-treating furnaces. This metal is paid for by companies every one of which could use the money so expended to the betterment of their product rather than writing it off in the profit-and-loss column and passing the tariff on to the ultimate consumer. American industry quite frequently puts up with undue waste to obtain production and perhaps the greatest

waste in the metal-working industries, which can be directly attributed to ignorance and neglect, is the waste of metal consumed in the heat-treating processes. This waste can never be entirely eliminated, but it may be greatly reduced. (*The Iron Age*, vol. 105, no. 11, Mar. 11, 1920, pp. 729-731, de)

## MACHINE PARTS

**A NEW NUT LOCK.** A new form of locking washer for bolts and nuts has just been brought out by the Palnut Company, Limited, of 6 Great St. Helens, London, E. C. 3, and, although we have not yet had an opportunity of testing its efficacy thoroughly, the principles on which it is designed appear to us to be sound. The washer is a simple stamping which takes the form of an inverted dish, with the edge turned up in such a way as to make a hexagonal rim. The center of the dish is pierced for the passage of the bolt, and there are half a dozen radial slots which divide the dish up into sector-like teeth connected together round the rim. The teeth are so stamped that when the washer lies on the top of a nut their apices follow the contour and project well into a single thread on the bolt. All that is necessary to put the washer in action is to screw it down tight above the nut to be locked. There is a natural tendency for the dish to flatten out when it comes into contact with the nut when forced down by a spanner. As the sector-shaped teeth cannot expand outward during the flattening process, they dig inward into the thread of the bolt, and thus obtain, so it is claimed, a very secure hold. On the other hand, if the nut tends to slack back, it will produce the same flattening effect, and the grip of the washer will be increased so long as it does not turn with the nut. In order to prevent that happening, that part of the washer which beds on the nut is formed with a smooth, rounded surface, with the object of insuring that the friction between the nut and washer shall be reduced to a minimum. The washer can, of course, easily be removed by means of a spanner. There is just one little matter in which we think that the washer might be improved. It is that it should be stamped plainly with the word *top*, or some other indication as to which way up it is to be used. The device would be valueless if put on the bolt upside down, and the perverseness of mechanics in the use of lock nuts is proverbial. (*The Engineer*, vol. 129, no. 3343, Jan. 23, 1920, p. 102, d)

## MACHINE TOOLS

### Multiple-Way Drilling Machines, Heavy-Duty Type, with Chip-Protection Device on Inverted Head

**THE FOOTE-BURT "WAY" DRILLING MACHINES, J. V. Hunter.** Multiple-way drilling machines are a comparatively recent development. The early types had a single vertical column supporting the work jig on which ways were planed for the travel of the saddles of both the upper and inverted drilling heads. The side heads were carried by comparatively light wing brackets bolted to each side of the column, which gave the machine a somewhat spidery appearance. About 1912-1913 these machines were improved and built more substantially. Among other things, the numerous individual oil cups of the older type were supplanted by gang sight-feed oilers with feed pipes to the various bearings; and a year or two later a provision was introduced to avoid the troubles caused by chips and dirt which work into the bearings of the inverted spindle head.

This head (Fig. 6) is now protected at the top by a sloping shield *A*, which tightly surrounds the spindle and prevents the accumulation of chips.

Below the shield are two plates, *B* and *C*, spaced a fraction of an inch apart where they surround the spindles and bolted together with an airtight flange around the outer edges. At each end of these plates is an air-hose connection; from one of these a blast of air can be blown, the exhaust taking place through the other, and all fine dust which enters this place is blown out, thus preventing its reaching the inner bearings. In addition to this each spindle is surrounded by a tapered cone *D*, which fits over

a stationary sleeve *E* that extends through the top shield to the plate *B*. The sleeve *E* is stationary, so no wear occurs between it and the shield.

The appearance of the latest model of a four-way drilling machine is shown in Fig. 7. Here the base is wide and heavy, supporting a full-width column of such proportions that no side arms are required. The single oil pump in the base handles practically the entire oiling.

FIG. 6 CHIP-PROTECTION DEVICE USED ON INVERTED HEAD OF THE FOOTE-BURT MULTIPLE-WAY DRILLING MACHINE

In addition to this, drill levers *A* (Fig. 7) automatically reverse the feed to draw out the drills rapidly on the completion of their cut.

One of the latest machines carries 61 active spindles. In addition to the four-way there is a three-way drilling machine, such

FIG. 7 LATEST MODEL OF FOOTE-BURT FOUR-WAY DRILLING MACHINE

as would be necessary for drilling the automobile-engine oil pan. It is simpler than the four-way machine because of the absence of the inverted spindle head, but does not materially differ from it otherwise. (*American Machinist*, vol. 52, no. 10, March 4, 1920, pp. 485-487, 8 figs., d)

## MANAGEMENT

## Fatigue, Its Character and Forms; Tiredness; Fatigue and Accidents

FATIGUE AND ITS EFFECT ON PRODUCTION, A. Vautrin. Discussion of the nature of fatigue, its forms and degrees, and its influence on productivity of labor, accidents, etc. The distinction is established between fatigue as an objective phenomenon and the subjective feeling of fatigue, or tiredness.

It has been known for some time and experimentally established by Kraepelin that all work done by man, whether physical

FIG. 5 DISTRIBUTION OF ACCIDENTS IN THE CHEMICAL INDUSTRY DURING THE WORKING DAY IN THE YEARS 1897-1907

Hours Worked and Percentage of Employees Injured During Each Hour

FIG. 9 DISTRIBUTION OF ACCIDENTS IN A GERMAN CABLE FACTORY THROUGHOUT THE WORKING DAY

or mental, is accompanied by a series of reactions which either favor its continuation or oppose it. The most important of the reactions opposing the tendency to continue working is known as fatigue, and may be of a physical or mental character or a combination of the two.

As regards its physical nature, it appears that all work produces in the body substances (chemical or organic) which exert gradually a narcotic effect on the central organs of the nervous system. In fact, Weichardt claims to have found present in animals a poison produced by fatigue which he calls kenotoxin.

Fatigue may be either physical or mental. In physical work certain groups of muscles are set in action, thereby producing a corresponding excitation in the central nervous system. Muscular fatigue takes place, therefore, partly on the muscular periphery and partly at the brain center, and the more demand is made on

the brain center, the greater the final fatigue. Purely mental work creates a demand on the large brain, which means a gradual exhaustion of the gray matter and a certain demand on the nervous ganglia connected therewith. In either case, however, sooner or later exhaustion of the organs brought into action follows.

Moreover, there is a close connection between physical and mental fatigue, and it is a well-known fact that when the body is overtired for any considerable length of time, this also reduces the ability of the brain to do mental work. The reason for this is clear. All work may be physiologically considered as a process of consumption which calls into play not only the organs directly producing the work, but, more or less, all the energy reserves of the body. Hence bodily exhaustion will gradually lead also to mental exhaustion, and an overburdening of one part of the body by products of fatigue will necessarily sooner or later affect the operating ability of all the other parts of the body.

Fatigue is only a moderate degree of the lowering of the producing ability of the body due to exhaustive work. A greater degree thereof is known as exhaustion, and the difference between the two is stated as follows: Fatigue leads to the lowering of the ability to perform work; exhaustion represents a state at which the performance of work becomes entirely impossible. Physiologically, exhaustion represents such an accumulation of the products of fatigue that the body is unable to reconstruct itself for the time being.

A clear difference must be made between fatigue, which is an objective phenomenon and represents the actual failing in the ability to perform work, and the subjective feeling of fatigue, namely, tiredness. Whereas fatigue is produced by the actual physiological processes of exchange of materials in the body, tiredness may be the result of various conditions and circumstances often lying entirely outside of the effort to produce work. Fatigue is a physiological phenomenon; tiredness, psychological. It may be due to lack of interest in the work performed, outside happenings in the life of the workman, etc.

FIG. 10 FREQUENCY OF ACCIDENTS IN THE VARIOUS DAYS OF THE WEEK COMPUTED PER 100 INJURED OR KILLED PERSONS

The degree of tiredness depends mainly on the condition of the workman, and the same amount of effort will produce a greater tiredness in a weak man than in a strong man, in a man poorly nourished than in one well nourished, and in boys and women than in grown-up men.

**Fatigue and Accidents.** The paper presents a number of facts in confirmation of the claim often brought out before that there is a distinct connection between fatigue and accidents, although the author makes it clear that he does not consider accidents as being due to fatigue exclusively.

From his data it would appear that in the hours when the

fatigue of the workman is still slight there are scarcely any accidents, while in the sections of the working day or week, when the fatigue has grown to an appreciable extent, the number of accidents is more than double the average. Figs. 8 to 10, together with tabular data in the article, would indicate that interruption of the working day by rest periods reduces accidents very materially, and that of all the days of the week, Saturday, the day when fatigue is at its climax, is the worst day from the point of view of accident occurrence. This is particularly apparent in plants which do not employ the Saturday half-holiday.

The following statistics were collected in Lower Frankonia in 1895:

Length of working day, hours	9½	10½	13	over 13
Accidents per 100 workmen	1.1	2.6	13.2	17.0

In printing establishments the accidents for the years 1910 to 1913 were on an average distributed in the following manner throughout the days of the week:

Sunday	136	Thursday	543
Monday	535	Friday	580
Tuesday	583	Saturday	585
Wednesday	530		

(*Technik und Wirtschaft*, published by the Verein deutscher Ingenieure, vol. 12, no. 11, Nov. 1919, pp. 748-758, 3 figs., g)

## MARINE ENGINEERING

### Concrete Ships Still an Experiment, Reports American Concrete Institute

**PRESENT STATUS OF THE CONCRETE SHIP.** The original program of concrete-ship construction of the Emergency Fleet Corporation was reduced after the armistice to a total of fourteen vessels, and in October 1919 contracts for two 7500-ton cargo vessels were cancelled.

At the present date there are in service three 3500-ton cargo vessels and one 3000-ton cargo vessel, three 7500-ton tankers and twenty-one 500-ton canal barges built by the Railroad Administration under the supervision of the Emergency Fleet Corporation. The remaining vessels are in various stages of completion and are expected to be in commission by next summer.

In general, it is stated that in carrying out this program no construction problems were encountered which were not successfully met. The experience of the vessels in service thus far indicates that for cargo vessels there is ample structural strength, and that the barge is a much simpler problem in concrete than in usual materials.

On the other hand, it was not found that reinforced-concrete hulls could be built with greater speed than steel hulls, the average time of constructing the concrete hull being seven months.

In service concrete ships stood up quite well. In fact, there is generally less vibration in concrete ships than in corresponding steel ships, and also a considerable increase in the period of roll, which is desirable and is apparently due to the fact that these vessels have a larger moment of inertia around longitudinal axis than steel ships, due again to the mass of the concrete shell being considerably greater than the mass of the shell in a steel ship.

On the other hand, experience seems to indicate that these vessels are unable to withstand severe concentrated blows on the shell without the shattering of the concrete.

Impact, which in the case of a steel ship would probably only cause indentation to the plates, in the case of the concrete ship is apt to cause a shattering of the concrete over the area adjacent to the point of impact.

Repairs, especially in the case of barges, are, however, relatively simple and can be effected with little loss of time and at small cost.

The dead-weight capacity of the concrete ship was found to be lower than expected, the ratio of dead-weight capacity to displacement being on the average little more than 0.50. Furthermore, in the case of a steel ship and a concrete ship having the same dead-weight capacities, the concrete ship because of the

greater weight of the ship itself must have greater dimensions than the steel ship, and in consequence must have greater hold spaces. For heavy-weight cargoes such as steel, coal or oil, in which the dead-weight capacity is reached before the hold spaces are filled, steel has obviously an advantage over concrete as a material of construction, assuming that construction and operating costs are equal. For bulky cargoes, such as ordinary goods, cotton, fruit or other materials for which the space required exceeds about 70 cu. ft. to the ton, the concrete ship will actually carry more dead weight than the steel ship for the reason that the hold spaces of the steel ship will be filled before dead-weight capacity is reached.

The report expresses the opinion that no definite conclusions should be drawn as yet from the experience of these vessels; and that the only general conclusion therefrom seems to be that it is possible to construct ships of concrete in about the same time, and for approximately the same cost as corresponding steel ships, which would indicate that with more experience in the art it will be possible to reduce both the cost and the time for construction. As regards the length of life of concrete ships, no sufficient data are available, and the brief experience of vessels afloat has disclosed no serious inherent weakness to shorten the life of a concrete ship. (Report read at the Convention of the American Concrete Institute, at Chicago, Feb. 16-18, 1920, by Committee on Reinforced Concrete Barges and Ships, H. C. Turner, Chairman. Abstracted through *Engineering News-Record*, vol. 84, no. 10, Mar. 4, 1920, pp. 463-464, g)

## PHYSICS

### Rate of Propagation of Flame in Mixtures of Methane and Air; Photographic Analysis of the Flame; Detonation Wave

**THE PROPAGATION OF FLAME IN MIXTURES OF METHANE AND AIR, PT. I.—HORIZONTAL PROPAGATION,** Walter Mason and Richard Vernon Wheeler. In a previous paper the authors discussed the initial "uniform movement" of flame in gaseous mixtures. The uniform movement, however, is only one phase in the propagation of flame and is of comparatively short duration. The speeds attained by the flame during its régime are slow compared with the speeds during other phases in the propagation of flames in mixtures wherein no detonation wave has developed.

A knowledge of the speeds of flame in such mixtures as methane and air is of considerable importance, for example, in connection with the safe working of coal mines and also indirectly for internal-combustion-engine design.

The present paper describes experiments relating to phases other than the uniform movement during the horizontal propagation of flame in mixtures of methane and air. The experiments were carried out in tubes of different dimensions and materials, measurements of speeds having been made by the "screen wire" method. Supplementary information was obtained by photographic analysis of the flames.

The experiments were carried out first on ignition at the open end of a tube closed at the other end; next, ignition at the closed end of a tube open at the other end; and finally, ignition at one end of a tube open at both ends.

Taking the case of ignition at the open end of a tube closed at the other end, the initial phase of propagation of flame constitutes the "uniform movement."

The linear duration of this phase is controlled by such factors as influence the establishment of resonance in the column of gases in the tube, among these being the speed of the flame and hence the composition of the inflammable mixture, length, diameter and uniformity of bore of tube. Eventually, as a direct outcome of the establishment of resonance, the flame front acquires a periodic undulatory motion, leading sooner or later to violent vibrations which vary considerably in amplitude but remain periodic.

During the vibratory movement the oscillations of the flame are of wide amplitude and the mean speed of translation of volume is considerably enhanced.

The vibratory movement is also an excellent example of the effect of agitation or turbulence in accelerating the translation of flame through a gaseous mixture. The effect is a mechanical one. During each forward impulse the flame is drawn rapidly through previously unburned mixture by reason of the motion acquired by the resonating column of gases. In a certain degree also the forward motion of the flame is assisted by the expansion in volume of the burning gases, especially when the flame is at some distance from the open end of the tube, so that the escape of the expanded gases there is retarded.

The two other cases are discussed in the same manner. The most important one probably is that of ignition at one end of a tube open at both ends.

In that case it was found that the speed of the flame in all mixtures except the limit mixtures increases continuously over the whole distance traveled, and it seemed possible that the detonation wave might be developed if the flame could travel far enough.

In tests with a steel tube 15.25 m. long, it was found that the flame had acquired a vibratory character after traveling over the length of the tube. The length of the tube was then increased to 90 m. in the expectation that a greatly increased distance of travel would produce regular recognizable vibrations of large amplitude. The results confirmed this expectation. The propagation ultimately become strongly vibratory, but the early stages of the propagation were deeply modified by the increased length given to the tube. Instead of increasing rapidly in speed from the beginning as with the shorter tube, the flames now travel from the point of ignition at a constant and comparatively slow speed over a distance of between 12 and 15 m. and then began to vibrate. The vibrations acquired their greatest amplitude about half way along the tube (as was the case with the shorter tube) and continued throughout the remaining distance.

Of these three conditions under which the ignition of mixtures of methane and air has been effected, the one which would appear to lead to the most disastrous results in industry is the third, that is, ignition at one end of a tube or gallery open at both ends.

The fastest speed of flame acquired in any experiment was about 60 m. per sec. and was of short duration. The experiments have not, however, shown that a detonation wave cannot be developed in mixtures of methane and air at normal temperatures and pressure. On the contrary, the experiments with the long steel tube indicated that such an eventuality is possible. (*Journal of the Chemical Society*, vols. 117 & 118, no. 687, Jan. 1920, pp. 36-47, 2 figs. in text and 3 plates, eA)

**THE PROPAGATION OF FLAME IN COMPLEX GASEOUS MIXTURES.** Wm. Payman. It is customary to describe the inflammation of a gas mixture containing, for example, hydrogen and oxygen as the "burning of hydrogen in oxygen." This phrase is purely a relative one, and it is equally correct to regard the combustion as the burning of oxygen in hydrogen. Thus, the upper limit of inflammability of hydrogen in oxygen is the lower limit of inflammability of oxygen in hydrogen.

Mixtures of a combustible gas with air can be considered in a similar way and burning of hydrogen in air may be considered as burning of oxygen in a mixture of nitrogen and hydrogen.

For purposes of thoroughly investigating the mode of combustion of complex inflammable gas mixtures, it is desirable to examine their behavior with "atmospheres" other than air, the simplest problem being the combustion of a pure inflammable gas such as methane in pure oxygen.

The present research deals, therefore, with mixtures containing more oxygen than air and with mixtures with pure oxygen, the subject under investigation being mainly the initial uniform movement of flame which is supposed to be mainly effected by the conduction of heat from the burning to the adjacent unburned layer of gas mixture as different from what is known as "detonation wave."

If we neglect losses of heat to the walls of the containing vessel, the speed of propagation of flame during the uniform movement

can be regarded as depending mainly on two factors, namely, (1) the rate of conduction of heat from layer to layer of the mixture, which in turn depends on the difference in temperature of the burning and the unburned gases and on their thermal conductivities, and (2) the rate of reaction of the combining gases, which for a given combustible gas will vary with the composition of the mixtures (presumably according to the usual laws of mass action) and with the temperature produced by the reaction. A third factor might be added, namely, the ignition temperature of the mixtures, but this is perhaps dependent on the other factors.

The mixture of hydrogen and air for complete combustion, that is to say, the mixture having the greatest heat of combustion, contains 29.6 per cent of hydrogen, but the mixture in which the speed of the uniform movement of flame is greatest contains about 38 per cent, or nearly 10 per cent in excess.

Two series of determination of the speed of the uniform movement of flame in mixtures of oxygen with an atmosphere of nitrogen and methane and one of nitrogen and hydrogen have indicated that a displacement of the maximum speed mixture is toward mixtures containing an excess of oxygen. Further tests with combustible gases burning in air have shown that the addi-

FIG. 11 CURVES OF SPEEDS OF UNIFORM MOVEMENT OF FLAME IN VARIOUS MIXTURES OF METHANE AND "ATMOSPHERES"

tion of either combustible gas or oxygen to the basic mixture results in an increase in speed of the flame; and furthermore, in accordance with the laws of mass action, the displacement is greater on the addition of oxygen than on the addition of methane, due to the fact that the combination of one molecule of methane with two molecules of oxygen results in complete combustion. On the other hand, the displacement, according to the same laws, should be less with the oxygen than with hydrogen since two molecules of hydrogen combine with one molecule of oxygen, and experiment shows this deduction to be correct.

The speeds of uniform movement of flame in mixtures of methane with atmospheres containing 13.7, 22, 33, 50, 66 and 100 per cent of oxygen have been determined, some by means of an automatic commutator and single recording stylus, some by delicate Deprez indicators and the fastest speeds photographically. The results of the determinations are given in tables and also in Fig. 11.

The most striking results are those for mixtures of methane with pure oxygen. Here the maximum speed of the uniform movement of flame is attained with the mixture containing methane and oxygen in combining proportions ( $\text{CH}_4 + 2\text{O}_2$ ). The result is a sharp distinction from what obtains when the detonation wave is developed in mixtures of methane and oxygen, for the mixture in which the speed of the detonation wave is greatest contains equal proportions of methane and oxygen.

The retarding effect of addition of methane to the mixture for complete combustion ( $\text{CH}_4 + 2\text{O}_2$ ) is well illustrated by photographs given in the original article. In such a case, either methane or oxygen acts exactly like an inert gas, such as nitrogen, and in fact, methane, having the highest specific heat of the three, has the greatest retarding effect.

In the latter part of the article the writer gives the method of

calculating mixtures so as to obtain given uniform speeds of flame movement. (*Journal of the Chemical Society*, vols. 117 & 118, no. 687, Jan. 1920, pp. 48-58, 6 figs., *et al.*)

## POWER PLANTS

### Ash- and Coal-Handling Equipment

**ASH- AND COAL-HANDLING EQUIPMENT**, W. O. Rogers. In an article entitled *Power Drives for Rolling Mills*, the writer describes an interesting system of ash- and coal-handling equipment installed at the new power plant of the Republic Iron and Steel Company at Youngstown, Ohio. Ashes from the stokers of the boilers are deposited in an individual three-outlet iron ash hopper lined with red brick. The outlet of the ash hopper is provided with gates (Fig. 12) operated on rollers and actuated pneumatically by a plunger controlled by a four-way valve. The ashes

conveyor 65 ft. long, center to center, and 36 in. wide. This conveyor has a capacity of 180 tons per hour at a speed of 40 ft. per min. Power to operate it is taken from the crusher shaft transmission by means of a chain drive to the hoist countershaft of the conveyor drive.

The crusher is of the four-roll type, each roll being 36 in. in diameter and 36 in. face. One pair of rolls is held rigidly in position, while the other pair is provided with heavy coil springs strong enough to press the coal and yet permitting of giving in case a foreign substance is encountered. The rolls and apron conveyor are operated by a 100-hp. compound-wound motor at 850 r.p.m. The capacity of the crusher, with run-of-mine bituminous coal crushing to 90 per cent  $\frac{3}{4}$ -in. size, is 180 tons per hour.

The article contains also a description of the boiler house and furnaces with their stokers. (*Power*, vol. 51, no. 8, Feb. 24, 1920, pp. 291-296, 5 figs., *d*)

### Tests of Canadian Fuels; Distribution of Heat Losses; Factors Affecting Efficiency of Boiler Furnaces

**RESULTS OF 41 STRAING TESTS CONDUCTED AT THE FUEL-TESTING STATION, OTTAWA.** The paper gives results made on tests with Canadian coals and as such is mainly of local interest. Some remarks are, however, of general interest and are reported here.

The tests were conducted in a Babcock & Wilcox water-tube boiler having 677 sq. ft. of heating surface. Some of the tests were conducted on a grate area of 23 sq. ft. with an air space of  $\frac{1}{4}$  in. between the bars; others on a grate area of 21 sq. ft. with an air space of  $\frac{1}{2}$  in. between the bars.

As regards losses, the following remarks are found in the report. The principal heat loss was that due to the total heat of the flue gases, which, in this case, does not include that due to the uncondensed steam. The variation of the loss due to the escaping hot gases for approximately the same boiler output is due almost entirely to the change in the amount of excess air. A figure is introduced showing the relation between the ratio of the flue-gas total heat loss to the heat usefully employed for steam raising and the ratio of the total air supplied to the air whose oxygen content is combined with the fuel (this relation is expressed as a straight line). This air ratio is calculated from

$$\text{the flue-gas analysis, and is equal to } \frac{21}{21 - O_2 \frac{79}{N_2}} \text{ where } O_2 \text{ and } N_2$$

represent the volumes of oxygen and nitrogen in the flue gas, and  $\frac{21}{79}$  the ratio of oxygen to nitrogen in the atmosphere. The

expression  $\frac{21}{100} \left( \frac{100 + XL}{X(1 + L)} \right)$  represents the ratio of air supplied

to air required in terms of the carbon dioxide content of the flue gas ( $X$ ) and the factor  $L$ , which depends upon the chemical constitution of the coal, and is equal to  $\frac{3}{C} \left( H - \frac{O}{8} \right)$ , where

$H$ ,  $O$ , and  $C$  represent the relative weights of the hydrogen, oxygen, and carbon contents of the fuel. This expression holds good only for complete combustion of a fuel whose sole constituents—which pass off with the flue gas—are carbon, hydrogen and oxygen.

As regards the variation in excess air, it is found that the air ratio was less when using a grate of 21 sq. ft. area with  $\frac{1}{2}$ -in. air spaces than when using a grate of 23 sq. ft. area and  $\frac{1}{4}$ -in. air space for the same fuel, and approximately the same rate of steaming. On the other hand, it was found that the excess air increased with an increase of rate of combustion for the majority of coals.

While a change from the grate with small to one with larger air openings reduced the excess air loss, it was found that the loss due to unburned solid fuel increased for the trials with the

FIG. 12 ASH HOPPER AND ASH GATES AT THE ROLLING-MILL POWER PLANT OF THE REPUBLIC IRON AND STEEL COMPANY, YOUNGSTOWN, OHIO

are dumped into motor-operated cars having a capacity of 50 cu. ft. The loaded car is run to a hopper from which the ashes have elevated to the top of the hoist and automatically dumped into a chute leading to a bin from which they are loaded into railroad cars for removal.

The operation of the ash hoists is of interest. When the ash handler desires to elevate a load of ashes that has been dumped into the hopper, he presses a starting switch to start the 50-hp. d.c. motor. When the 70-cu. ft. capacity skip reaches the top, a resistance coil is cut in on the circuit, which causes the motor to slow down. When the ash bucket reaches the dumping position, the circuit is automatically cut and the bucket stops long enough to discharge its contents. By means of a relay switch on the control board, after the bucket has remained at the dumping position a sufficient length of time to dump, the current is automatically applied to the motor, which has been reversed by means of a limit switch, and the bucket is sent to its original loading position ready to receive another load. The cycle comprises a period of 2½ minutes.

Coal is delivered from railroad cars into a rack hopper, from which it is conveyed to the crusher by means of an apron-type

larger air space and that this loss tended to increase considerably with an increasing ash content.

Briefly then, burning coal on a grate with  $\frac{1}{4}$ -in. air spaces, tends to cause the loss due to solid unburned carbonaceous material to be less and the loss due to the escape of flue gases to be greater than when using a grate with  $\frac{1}{2}$ -in. air spaces.

The principal reasons for the variation in the radiation, and unaccounted-for loss, where the rate of steaming remains the same, are variations in the heat transmitted from the hot gases and incandescent fuel through the boiler setting, and in the variation of the undetermined combustible content of the products of combustion.

A number of figures are plotted in the original report showing the total loss due to radiation, unburned gases and the unaccounted-for loss. These figures are plotted on a base representing the ratio of the air supplied to that used for combustion. While no attempt has been made to plot a curve showing any general law, it would appear that the loss tends to decrease with an increased air supply.

An increase in the air-supply ratio may be expected, therefore, to be accompanied by a decrease in the loss due to incomplete combustion and by an increase in that due to the increased mass of gas escaping at a high temperature; and the efficiency of the boiler, based on the solid combustible consumed, will show the net result of the change.

In general, it would appear that the predominant effect of the increase in the air ratio for any particular fuel is to lower the efficiency, but this must not be considered in the light of an absolute law. (*Bulletin No. 27, Mines Branch, Department of Mines, Canada, Ottawa, 1920, pp. 3-83, 41 charts, e.1*)

**BOILER AND FURNACE TESTING, Rufus T. Strohm.** Recommendations for simple tests of a particular character, the purpose of which is to find out how efficiently the boiler is working.

The test is of the nature of an evaporation test and comprises the determination of the total weight of coal used during the test, the duration of which is recommended as 8 hr.; the total weight of water fed to and evaporated by the boiler; the average temperature of the feedwater; the average steam pressure in the boiler.

The methods of determining these factors and simple formulæ for calculating results are given, as well as recommendations for using the results. (*Bureau of Mines Technical Paper 240, reprint of Engineering Bulletin No. 1, U. S. Fuel Administration, Washington, 1920, p*)

## PUMPS

### High-Vacuum Mercury Pump with Provision for Storing Gases Exhausted

**HIGH-VACUUM MERCURY PUMP WITH PROVISION FOR THE PRESERVATION OF THE EXHAUSTED GASES, A. Beutell and P. Oberhoffer.** Both mercury pumps of the Sprengel type and such mechanical pumps as the Gaede have the disadvantage of possessing no provision for conveniently collecting and preserving the gases exhausted from a high vacuum. This becomes of importance now that a considerable amount of interest has been aroused in the subject of gases occluded in minerals and metals. In the present article a pump is described with which it is possible to collect the gases exhausted from a high vacuum. It is stated that the new arrangement does not materially affect the rate of operation of the pump; thus, the 500-cc. container may be exhausted to a pressure of 0.0007 mm. in 10 min. and to a pressure of 0.00011 mm. in 20 min. Furthermore, it is not desirable to collect the exhausted gases, the operation of the pump is not affected in any way.

As seen from Fig. 13, the pump is of the water-jet type, but the exhausted gases are not directed as usual into the water jet at *N*. Instead, there is inserted the small tank *E* between the downward tube *Fa* and the upward tube *St*, this container being equipped with a three-way cock. The upward tube *St* is provided at its lower end with an expanded section, the purpose of which is to

prevent the flow of air from *L* into the container *E*. This made it necessary to increase the dimensions of the container *N*, the purpose of which is to take up the mercury displaced by the gas collected in *E*.

Because of this the amount of mercury used in the present pump is about 100 cc. as compared with about 20 cc. for similar pumps previously used and having no provision for the collection of exhausted gases.

Instead of the asbestos stopper formerly used for regulating the air admission at *L*, there is now welded in there a thick-walled capillary tube protected against penetration of dirt into it by an

FIG. 13 BEUTELL AND OBERHOFER HIGH-VACUUM PUMP WITH PROVISION FOR THE PRESERVATION OF EXHAUSTED GASES

other glass tube closed at one end. The three-way cock *N* at the top of the tube likewise employs a capillary tube instead of the normal asbestos stopper for the purpose of safely admitting air to the pump against the vacuum therein.

The operation of the pump does not materially differ from that of similar pumps previously described. In addition, the article describes an apparatus for gas analysis. (*Chemiker-Zeitung*, vol. 43, no. 125, Oct. 16, 1919, pp. 705-706, 4 figs., d)

## RAILROAD ENGINEERING

### Steam and Electric Propulsion for Railroads Compared; How the Railroads Utilize Their Fuel; Standardization of Frequencies; Electric Locomotives

**THE LAST STAND OF THE RECIPROCATING STEAM ENGINE, A. H. Armstrong.** By "the last stand of the reciprocating steam engine" the author, who is Chairman of the Electrification Committee, General Electric Company, refers to the steam operation of railroads.

In brief, he claims that where applicable the electric locomotive

is more reliable and more economical from the point of view of fuel consumption. He makes a reservation, however, to the effect that many roads of lean tonnage should not be immediately electrified, as they would render no adequate return upon the large capital investment required.

To illustrate the present situation he gives Table 1, showing the subdivision of the tonnage passing over the tracks of our railways (The source of the table is not indicated).

The first four items, representing nearly 85 per cent of the total ton-miles made during the year 1918, may be regarded as fundamentally common to both steam and electric operation. By introducing electric propulsion the last four items are considerably cut down, and it is claimed that approximately 12 per cent or about 150 billion ton-miles at present hauled by steam engines over the roads will be eliminated. This means that if all American railways were completely electrified they could carry one-fifth more revenue-producing freight tonnage with no change in present operating expenses or track congestion.

Another table would indicate that a quarter of all the coal mined in the United States is consumed by the railways, and the author claims that this is done with extreme wastefulness. This claim is

TABLE 1 TOTAL TON-MILE MOVEMENT  
(All Railways in United States—Year, 1918)

	Per Cent	Ton-Miles
1 Miscellaneous freight cars and contents.....	42.3	515,000,000,000
2 Revenue coal cars and contents.....	16.23	197,000,000,000
3 Locomotive revenue, driver weight only.....	10.90	132,300,000,000
4 Passenger cars, all classes.....	16.13	196,000,000,000
Total revenue, freight and passenger.....	85.56	1,040,300,000,000
5 Railway coal, all classes.....	5.90	60,000,000,000
6 Tenders, all classes.....	6.50	78,800,000,000
7 Locomotive railway coal.....	0.39	4,700,000,000
8 Locomotive, non-driving weight.....	2.55	31,000,000,000
Total non-revenue.....	14.44	175,100,000,000
Grand total (all classes).....	100	1,215,400,000,000

TABLE 2 COAL REQUIREMENTS FOR U. S. RAILROADS IN  
1918 REFERRED TO ELECTRICAL UNITS

Total ton-miles, 1918.....	1,215,400,000,000
Watt hours per ton mile.....	40

Reduction by electrification.....	146,000,000,000
Total ton-miles electric.....	1,069,400,000,000
Kw-hr. electric at 40 watts.....	42,776,000,000
Coal on basis 2½ lb. per kw-hr., tons.....	53,500,000
Equivalent railway coal, 1918, tons.....	176,000,000
Saving by electrification, tons.....	122,500,000

based on tests made upon the Rocky Mountain Division of the C. M. & St. P. Ry. to determine the relation existing between the horsepower-hours of work done in moving trains and the coal and water consumed on the steam engines in service. From these tests it would appear that the total actual coal consumed under the engine boiler in 24 hr. divided by the actual work performed by the engine is equivalent to 10.18 lb. per hp-hr. at the driver rims. These tests have also shown that the coal consumed while doing useful work was raised 30 per cent by stand-by losses. In electrical constants this was found to be equivalent to 7.56 lb. of coal per kw-hr. at power supply on a basis of 55 per cent efficiency.

From this the author proceeds to an estimate of the cost in pounds of coal to do the same work electrically, taking the condi-

tions existing on certain western railroads. To do this, the ton-mile values of Table 1 are reconstructed into those of Table 2. From this he proceeds to the construction of Table 3 showing the saving of coal by electrification again on the basis of Table 1.

The startling conclusion arrived at is that approximately 122,500,000 tons of coal, or more than two-thirds the coal now burned in our 613,000 steam engines, would have been saved during the year 1918 had the railways of the United States been completely electrified along lines fully tried out and proved successful today.

The author claims this estimate is probably too conservative as no allowance has been made for the extensive utilization of water power which can be developed to produce power more cheaply than by coal in many favored localities. On the other hand, one should bear in mind his previous statement that many roads of lean tonnage would render no adequate returns upon the large capital investment required by electrification. It would appear, therefore, that essentially the question is more economic than technical.

Of interest in this connection is a passage at the end of the paper referring to the study of the congested tracks of the Baltimore and Ohio Railroad between Grafton and Cumberland. Company coal movement in coal cars and engine tenders constituted over 11 per cent of the total ton-mileage passing over the tracks.

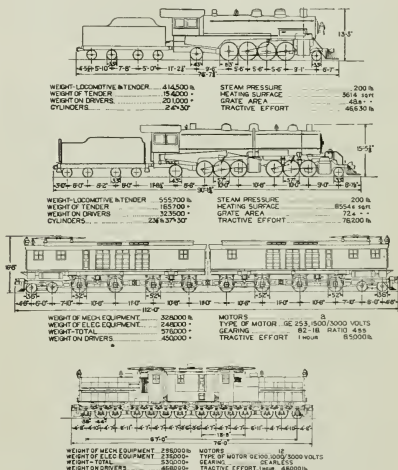

FIG. 14 DIAGRAMMATIC COMPARISON OF STEAM AND ELECTRIC LOCOMOTIVES

In other words, due to the very broken profile of this division, the equivalent of one train in every nine is required to haul the coal burned on the engines.

It is assumed that with the electric-locomotive operation the three tracks now badly congested with present steam-engine tonnage could carry 80 per cent more freight.

Attention is called to Fig. 14 which gives an interesting comparison between steam and electric locomotives. (*Journal of the American Institute of Electrical Engineers*, vol. 39, no. 3, Mar. 1920, pp. 209-218, 11 figs. d)

The United States Bureau of Mines announces that it has developed a novel method for giving a danger warning in mines in which compressed air is used throughout the workings. An ill-smelling substance is injected into the compressed-air line and within a few minutes the odor is spread throughout the mine.

## STEAM ENGINEERING (See Railroad Engineering)

## VENTILATION

## Ozone Air Purification

OZONE AS THE SOLUTION OF THE FRESH-AIR PROBLEM, E. S. Hallett. Description of installations tested out in the public schools of St. Louis, Mo. The Head of the Hygiene Department of the Board of Education of St. Louis came to the Building Department with the complaint from one of the downtown schools that the air was so bad in some rooms that teachers threatened to resign on the advice of their physicians. The writer proposed to the Hygiene Department to test the application of ozone.

The ozone apparatus was set up in the air passage between the air washer and fan, and regulated to produce just sufficient ozone to be barely detected by the odor on entering the building, but not enough to make one conscious of an odor. The result was the actual disappearance of all the stuffy conditions and bad smells complained of. The teachers stated that the conduct of the children as to lessons and behavior was noticeably better. Colds and coughs nearly disappeared. No contagious diseases developed during the six weeks' trial, although the influenza was epidemic at this time. In fact, during the period of an influenza epidemic, the attendance was 30 per cent higher than the general average attendance for this school.

The experiment was then transferred to a colored school having the plenum system with the Zellweger air-washing fan and with complete recirculation of the air. The ozone machine was set up just back of the fan, the ozone acting upon the water of the air washer as well. In this test the pupils and teachers were weighed weekly and a close inspection made by the staff physician of the Hygiene Department. About 75 per cent of the children gained in weight on an average of about one pound, about 5 per cent lost weight, while the rest suffered no change. Several very stout girls weighing about 170 lb. each lost from 5 to 8 lb. weight (total duration of test not stated). No indication of illness or discomfort was noted. No contagious diseases occurred in this school and colds were noticeably less.

The coal consumption was measured, and in comparison with days of equal outside temperature the coal used was almost exactly one half.

Agar plates were exposed in a room filled with pupils and showed an average count of bacteria of 225, which was extremely low, indicating that the ozone had destroyed the active germs of the air.

These and other tests during a year's period indicated that ozone destroys all odors resulting from the respiration, bodies and clothing of the children, and produces a mild exhilaration resembling that of a sea breeze or the air on a morning after a thunderstorm. It appears from limited data to be a preventive of influenza, and it is believed that its introduction in ventilation would probably remove the necessity for open-air schools now common in most cities.

The maximum concentration should be too low to give an ozone odor, and if used up to this concentration is safe for ventilation. Persons not used to ozone in air must be employed for detecting the air, as the sense of smell for ozone quickly declines when exposed to it.

The writer developed a standard which may be used in determining in advance the proper concentration for any given volume of air movement or for a given number of occupants in a room.

This standard was developed after ascertaining that with a given voltage and with a given thickness of dielectric the amount of ozone generated was proportional to the number of brush discharge points of the generator.

The most satisfactory apparatus uses 4000 volts alternating current from a static transformer, all included with the ozone generator unit, which uses a mica plate dielectric 0.040 in. in thickness and aluminum points spaced approximately  $\frac{1}{2}$  in. apart.

It was observed that 600 brush points made just enough ozone for 1000 cu. ft. of air from the blast fan.

This test was with rooms filled with 45 to 50 children much below the average in cleanliness. For rooms occupied by fewer people, the brush points or voltage should be reduced. If conditions are to remain constant, some points should be disconnected, but with varying conditions a controller should be installed to regulate the voltage by taking taps out of the primary of the transformers.

Where the air is recirculated in whole or in part, the ozone must be cut down to the point where no ozone odor is noticeable. In fact, the revitalizing of the air of the average school room when recirculating 90 per cent of the air will be effectively done with half the maximum stated above. The writer believes that the delay in the use of ozone in ventilation has been due to trials made with too high concentration and to the absence of any information on a means of control.

Ventilation for its final effect depends on the purity of the air surrounding the building, and if the building, such as a school or hospital, is located in an unhealthy neighborhood, ventilation is apt to do more harm than good. Ozone, by killing the germs in the air, practically creates clean air and is independent in its effect on the location of the building to be ventilated.

The writer proceeds to show a heating system designed in the light of these tests. It has no air washer. (Paper presented at the Annual Meeting of the American Society of Heating and Ventilating Engineers, Jan. 27-29, 1920, under the title, An Advance in Air Conditioning in School Buildings. Compare *Heating and Ventilating Magazine*, vol. 17, no. 2, Feb. 1920, pp. 25-29, 1 fig., ed)

THE DETECTION OF INVISIBLE OBJECTS BY HEAT RADIATION. In 1918 the United States Army started to devise methods for detecting men and inanimate objects which were at a higher temperature than adjacent things by means of the emitted radiation. A thermopile was placed at the focus of a parabolic mirror. The radiation from the warmer object fell on the mirror and was reflected to the thermopile where it produced an electric current which was observed by means of a galvanometer. It was possible to detect a man 600 ft. away. "A man lying in a depression in the ground at a distance of 400 ft. was detected unflinchingly as soon as he showed the upper part of his face above ground." Secret signaling could be carried on by covering and uncovering the face. This apparatus was sent to the A. E. F. in August, 1918.

An aeroplane at an altitude of 3500 ft. could be picked up by such an instrument and its course followed. A wisp of cloud produced confusion by causing as large a deflection as the aeroplane did, but the two possible causes were different in the way in which the galvanometer deflection began.

In an address before the Section on Physics of the American Association for the Advancement of Science, St. Louis, December 1919, Prof. Gordon F. Hull called attention to the rather peculiar fact that in the official manual for the U. S. rifle the value of the ballistic coefficient of the ordinary service rifle bullet of 0.30 in. caliber is given as 0.3894075, "as determined experimentally at the Frankford Arsenal." Commenting on this he said: "The experimental skill which can determine to an accuracy indicated by several places of decimals a quantity as highly capricious as the so-called ballistic coefficient, is of rather questionable value."

## CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

# ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

## Coöperative Research

AT PRESENT seven associations of manufacturers are supporting research at the Mellon Institute at Pittsburgh. The name of the association, the number of companies and the amount subscribed for the fellowship foundation in each case is given in the following table:

	Number of Companies	Amount
Magnesia Association of America.....	4	\$ 6000
Asbestos Paper Manufacturers Assn..	10	3500
Rex Spray Companies.....	9	3500
Laundry Owners National Association	2500	5000
Leather Belting Exchange Corporation	40	5000
Refractories Manufacturers Association	84	10000
Container Club.....	24	3500

The investigations on magnesia insulation are for the purpose of determining its heat-insulating value. The investigations for the Asbestos Paper Manufacturers are for the purpose of standardizing the specifications for asbestos textiles and asbestos millboard. The Rex Spray fellowship is for the purpose of improving the manufacture of insecticides. The Laundry Owners' fellowship is devoted to the investigation of water, soap, permanency of colors, stains and dyes. The Leather Belting fellowship is for the purpose of determining the comparative power-carrying capacities of leather belts with substitute belts. The fellowship of the Refractories Association is for the purpose of determining standard tests to be used in manufacturing. The Container Club fellowship is in connection with the development of a paper tester and the testing of fiber board with this instrument.

## A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulae or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

### Apparatus and Instruments A3-20 Gage for Small Pressures.

The Wahlen gage was developed by W. G. Wahlen of the Engineering Experiment Station of the University of Illinois. It is sensitive to 0.0001 in. of water. It is composed of a rigid base on leveling screws with two large glass bulbs communicating through a special inverted U-tube. One of the bulbs is controlled by a micrometer caliper. Alcohol of density 0.8195 is used in the bulbs and part of the U-tube. It is colored with aniline dye to give a red color. The upper part of the U-tube is filled with a mixture of turpentine and ligroin of density 0.810. The gages are first balanced at zero with both ends open. The pressure connection is then made and the movable carriage is adjusted to bring the meniscus in the U-tube to its reference point. By using a U-tube with legs of different sizes accurate observations may be made. This gage may be used with pitot tubes for the calibration of instruments or the measuring of low air currents. Address Engineering Experiment Station, University of Illinois, Urbana, Ill. C. R. Richards, Director.

**Apparatus and Instruments A1-20 Radiation Effects on Thermocouples.** In determining the temperature of the air in hot-air leaders of a warm-air furnace, the Experiment Station of the University of Illinois has found that the radiation from the thermocouples affects the temperature reading shown by them. The temperature of a leader was determined by a thermocouple when the leader was uncovered and when the leader was covered with hair felt. If the temperature of the air going to the leader was found to be the same in each case, the difference shown in the leader would represent the loss due to radiation. This was found to be 26 deg. Fahr. when the temperature observed was 195 deg. Fahr. Engineering Experiment Station, University of Illinois, Urbana, Ill. Address C. R. Richards, Director.

**Buildings A1-20 Vibration.** A preliminary report by the Aberthaw

Construction Company on the Effects of Vibration in Structures has been issued. This gives a statement of the research from 1133 replies in connection with this investigation. The report mentions the natural frequencies of vibrations, the method of recording vibrations, method and type of construction, the reduction of efficiency and production caused by vibration, experiments in various forms of mills, methods of absorbing vibration, methods of tracing vibration, types of building used and methods of design. Address Aberthaw Construction Company, 27 School St., Boston, Mass.

**Fuels, Gas, Tar and Coke A2-20 The Comparative Value of Fuels.** by M. K. Thornton, Jr., issued by the Texas Engineering Station, College Station, Tex. Address J. C. Nagle, Director.

FIG. 1 CURVES SHOWING EFFECT OF REGISTER TEMPERATURE ON LEADER CAPACITY

**Fuels, Gas, Tar and Coke A3-20 Wood.** The fuel value of wood is given by the Forest Products Laboratory. Two pounds of dry wood of any non-resinous species has the heating value of 1 lb. of good coal. Resin gives about twice as much heat as the wood. As the average amount of resin is 15 per cent, this increases the heating value 30 per cent. One cord of hickory, oak, beech, birch, hard maple, ash, elm, locust, long-leaf pine or cherry is equal to one ton of coal; and 1½ cords of short-leaf pine, Western hemlock, red gum, Douglas fir, sycamore and soft maple are equal to one ton of coal. Two cords of cedar, redwood, poplar, catalpa, cypress, basswood, spruce or white pine are equal to one ton of coal. Forest Products Laboratory, Madison, Wis. Address Director.

**Heating A5-20 Warm-Air Furnaces.** Bulletin No. 112 of the Engineering Experiment Station of the University of Illinois, on the Progress of the Warm-Air Furnace Research, by A. C. Willard, has been issued. The report describes the method of measuring temperature and allowing for the radiation effect, the method of measuring air at low velocities with anemometers and pitot tubes using the Wahlen gage accurate to 0.0001 in. of alcohol. Researches indicate that a square inch of leader pipe on the first floor has a far less heating and carrying value than that for second- or third-floor leader pipe. The tests indicate that the capacity of a warm-air furnace system is greatly reduced by dampening leaders to the upper floors. The temperature at register faces should be 175 deg. Fahr. The amount of heat delivered per square inch of leader area is given by the three curves in Fig. 1. The efficiency of the furnace as installed is shown by the curve in Fig. 2, below which is shown the arrangement of the installation. Engineering Experiment Station, University of Illinois, Urbana, Ill. Address Director C. R. Richards.

*Hydraulics A1-20* Sewage Sprinkler Nozzles and Coefficient for Discharge. The discharge from sewage sprinkler nozzles can be represented by the equation  $Q = C_d \sqrt{2gh}$  after the head on the sprinkler is greater than  $1\frac{1}{2}$  ft. At lower heads the coefficient decreases. The exponent of the head is practically 0.5. Seven different nozzles were tested with the following coefficients:

Chase square nozzles.....	0.648
Taylor round nozzles.....	0.656
Taylor square nozzles.....	0.656
Worcester round nozzles, 13/16 in.....	0.699
Worcester round nozzles, 11/16 in.....	0.675
Merritt square nozzle.....	0.598
Priestman-Beddoes round nozzle.....	0.569

*Internal Combustion Motors A1-20* Spark Plugs. The Fifth Annual Report of the National Advisory Committee for Aeronautics will contain a report on the properties and preparation of ceramic insulators for spark plugs. Report No. 53, in four parts, gives the results of research and development work conducted by the Bureau of Standards at the instance of the National Advisory Committee for Aeronautics. A discussion is given of the methods for measuring the resistance of insulators at high temperatures and the method finally adopted for this work is described. Re-

FIG. 2 EFFICIENCY CURVE FOR A FURNACE OPERATING AT VARIOUS REGISTER TEMPERATURES AND RATES OF COMBUSTION

sults of tests of a large number of insulating materials at high temperatures are tabulated and their significance discussed. The preparation and composition of ceramic insulators is outlined and compositions are given of new porcelains having superior properties. Results of an experimental investigation into the corrosion effects and permanency of various cements for spark-plug electrodes are discussed. The four parts of this Report are entitled as follows:

Part I Methods of Measuring Resistance of Insulators at High Temperatures, by F. B. Silsbee and R. K. Honaman.

Part II Electrical Resistance of Various Insulating Materials at High Temperatures, by R. K. Honaman and E. L. Fonseca.

Part III Preparation and Composition of Ceramic Bodies for Spark Plug Insulators, by A. V. Bleining.

Part IV Cements for Spark-Plug Electrodes, by H. F. Staley. Address National Advisory Committee for Aeronautics, Washington, D. C.

*Light A1-20* Reflectometer. The Bureau of Standards has developed a new reflectometer after extensive experiments. The instrument is to be used to determine the amount of reflection from walls to rooms. It consists of a small metal sphere from which a segment has been removed leaving about nine-tenths of its original surface. It is painted inside with a diffusing white paint and a beam of light is projected through a small hole in the wall to the surface which is to be tested. The test surface may be covered with the standard surface or with a flat surface painted with the same paint as the sphere. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

*Lubricants A1-20* Solid Lubricants. The Department of Scientific and Industrial Research of Great Britain has recently prepared a memorandum on solid lubricants. This can be obtained for sixpence from H. M. Stationery Office at No. 20 Abington St., Westminster S. W. 1, London, England. The subject is dealt with under the following headings:

- 1 Characteristics of Solid Lubricants
- 2 Action of Solid Lubricants
- 3 Analyses of Lubricating Graphites
- 4 The Grading of Graphite
- 5 Hot Bearings
- 6 Methods of Applying Solid Lubricants

7 Drawbacks to the Use of Colloidal Solid Lubricants

8 Observations on Results Obtained by the Use of Solid Lubricants.

*Mining A1-20* Concentrating Minnesota Wash Ores. A new machine for concentrating Minnesota wash ores. Bulletin No. 6 of the Engineering Experiment Station of the Minnesota School of Mines. Address W. R. Appleby, Director, Minneapolis, Minn.

*Mining General A2-20* Panel Systems of Coal Mining, by C. M. Young. A graphical study of the percentage of extraction by the panel system of coal mining. The paper shows that the greatest extraction with room 200 ft. long and 30 ft. wide on 50-ft. centers is only 57.05 per cent and with 40-ft. rooms 68.48 per cent. The Bulletin shows the reasons for low extraction, the advantages of high extraction and the method of investigating the percentage extraction. Engineering Experiment Station, University of Illinois, Urbana, Ill. Address Director.

*Properties of Engineering Materials A3-20* Boiler Plate at Elevated Temperatures. A series of tests on cold-rolled boiler plate at temperatures has just been made. The curves from the tensile tests show the same variations as those obtained with temperature increases on hot-rolled plates with the exception of the range from 475 deg. Fahr. to 675 deg. Fahr., where the proportional limit suddenly increases and the reduction of area shows a distinct decrease. The tensile strength also registers a sharp change. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

*Properties of Engineering Materials A5-20* Granite and Indiana Limestone. Investigations on the properties of commercial granites of the United States has been commenced and tests have been completed on twelve varieties used in the eastern part of the country. Seventy-two samples of Indiana limestone have been studied and the results are available for those interested in the subject. The summary gives the tensile strength, transverse strength, absorption, porosity and weight per cu. ft. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

*Properties of Engineering Materials A6-20* Over-Sanded Concrete. In order to make certain concrete mixtures more workable it has been proposed to introduce additional sand. The Bureau of Standards has investigated a 1:2:4 limestone concrete and a 1:3:5 mixture of the same substances. After 28 days the latter mixture gave 988 lb. per sq. in. while the former gave 768 lb. per sq. in. The latter sample took 487 lb. of cement per cu. yd. while the former took 508 lb. per cu. yd. This shows the advantage of over-sanding. Further tests are under way. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

*Wood Products A6-20* Gluing. When large glue joints are to be made, high strength of the whole joint is obtained by heating the wood for 10 or 15 min. to a temperature of 120 deg. Fahr. before gluing. Forest Products Laboratory, U. S. Forest Service, Madison, Wis. Address Director.

## B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problems for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

*Aircraft B3-20* Model Tests. The theory of model tests of flying boats. Address Curtiss Research Laboratory, Curtiss Engineering Corporation, Garden City, L. I.

*Aircraft B1-20* Static Pressure Gradients. The theory of static pressure gradients in wind tunnels; method of eliminating pressure gradients and short method of correcting for pressure gradients. Address Curtiss Research Laboratory, Curtiss Engineering Corporation, Garden City, L. I.

*Aircraft B5-20* Pressure Gages. Absolute pressure gage for wind-tunnel work. Address Curtiss Research Laboratory, Curtiss Engineering Corporation, Garden City, L. I.

*Aircraft B6-02* Cable Air Resistance. Tests on resistance of multiple airplane cables behind each other at varying amounts of separation. Address Curtiss Engineering Corporation, Garden City, L. I.

*Apparatus and Instruments B3-20* Absolute Pressure Gage for Wind-Tunnel Work has been designed and constructed at Curtiss Research Laboratory. Address Curtiss Engineering Corporation, Garden City, L. I.

*Chemistry, Inorganic B1-20* Fixation of Atmospheric Nitrogen. An investigation of a number of factors for increasing the efficiency of the process in the fixation of atmospheric nitrogen, by Prof. E. A. Lowe and F. K. Kirsten, Engineering Experiment Station, University of Washington, Seattle, Wash. Address C. E. Magnusson, Acting Director.

*Electrical Communication B1-20* Multiplex Radiotelephony. An investigation for sending five radio telephone messages from same antenna and reception of these through single antenna. F. M. Ryan, J. R. Tolmie, Roy Bach, A. Kalin, graduate students in City, L. I.

Electrical Engineering. Engineering Experiment Station, University of Washington, Seattle, Wash. Address C. E. Magnusson, Acting Director.

*Electric Instruments B1-20* Order and Amplitude of Harmonics in Voltage Waves. A method for determining the order and amplitude of harmonics in voltage waves by indicating meters. A wave analyzer is being constructed to apply this method. Prof. L. F. Curtiss, Engineering Experiment Station, University of Washington, Seattle, Wash.

*Electric Instruments B2-20* Oscillograph. A convenient timing device for use with the oscillograph. A convenient method for producing time waves of any desired frequency. J. R. Tolmie, Engineering Experiment Station, University of Washington, Seattle, Wash. Address C. E. Magnusson, Acting Director.

*Electric Power B1-20* Trunk Transmission Lines. An investigation on the need for trunk transmission lines on the Pacific Coast by C. E. Magnusson, Engineering Experiment Station, University of Washington, Seattle, Wash. Address C. E. Magnusson, Acting Director.

*Glass and Ceramics B1-20* Enamels. The Bureau of Standards is investigating the formation of fish-scaling in enamels on sheet steel and also the subject of the relation of the composition of the enamel to solubility in acids. They have made over 4000 sample enamel plates comprising 21 different enamels in the production of fish-scaling and 33 enamel compositions have been tested for the solubility in acids. One of the most important factors in producing fish-scaling is too severe heat treatment in firing the enamel. The composition of the enamel and the physical and chemical characteristics of underlying metal together with the method of melting the mixture and the shape and weight of the mixture are important factors. The work on the acid-resisting properties indicates that oxides which are chemically similar in nature do not have similar effects when incorporated in enamel compositions. Thus calcium chloride is not so good as barium oxide. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

*Heat B3-20* Evaporation from Liquid Surfaces. Address Curtiss Engineering Corporation, Garden City, L. I.

*Internal-Combustion Motors B3-20* Available Fuels. An investigation of available fuels for internal-combustion engines in the future using suggested manifold and heater for the application of high-boiling-point fuels. J. G. Vincent, Packard Motor Car Company, Detroit, Mich.

*Properties of Engineering Materials B10-20* Cables. Tramway Cable Loaded at One Point, by S. Herbert Anderson. An investigation to obtain equations which completely describe the conformation taken by a flexible chain or cable anchored with one end at a higher level than the other and loaded at any one point such as a tramway cable or logging skyline. Equations have been obtained for easy computation of tension at any point, maximum tension for given loading and position of load for maximum tension. Equation contains three constants or parameters, one of which is expressed in terms of the other two. Constants can be determined from weight of cable per unit of length, amount of load, and heights of end points above load. University of Washington, Seattle, Wash. Address C. F. Magnusson, Director.

*Textile Manufacture and Clothing B1-20* Methods of Determining the properties of cotton fibers with respect to their manufacturing properties. These methods are to be used in connection with determining the effect of the present manufacturing properties in the interest of higher-speed textile machinery and more economical use of cotton fibers. Textile Research Company, 34 Battery-march St., Boston, Mass. Address E. D. Whalen, Manager.

*Transmission B3-20* Wood Pulleys. An investigation of pulleys prepared from spruce. Pulleys built up in the same manner as hardwood pulleys. Density of the spruce fibers increased by compression at right angles to grain to one-half of original volume. Tests being made as to the effect of frictional driving power and investigations of mechanical strength, and are in charge of Prof. G. S. Wilson, Engineering Experiment Station, University of Washington, Seattle, Wash. Address C. E. Magnusson, Acting Director.

## C—RESEARCH PROBLEMS

The purpose of this section of Engineering Research is to bring together persons who desire cooperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring cooperation or aid will state problems for publication in this section.

*Automotive Vehicles and Equipment C1-20* Resistance of Automobile Bodies. Tests on resistance of automobile bodies at various speeds. Address Curtiss Engineering Corporation, Garden City, L. I.

## E—RESEARCH PERSONAL NOTES

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

*Heating E1-20* The work of the Engineering Experiment Station at Pennsylvania State College in connection with heating and ventilation is being conducted along the lines of obtaining the coefficient of heat transmission by means of the "Hot Box." This method gives the effects of conduction as well as the surface effects. The work is under the direction of Prof. A. J. Wood. Address Dean R. L. Sackett, Pennsylvania State College, State College, Pa.

*Heating E2-20* Warm-Air Furnace Research, by A. C. Willard. Among the various problems to be carried on in the researches connected with warm-air furnace heating may be mentioned the following:

Transmission, efficiency and capacity with various register temperatures with draft not to exceed 0.2 in. of water. The length of firing period is also to be investigated. The heat- and air-carrying capacities and heat losses in various kinds and sizes of leaders and stacks are to be investigated. Losses in boots and registers are to be determined as well as the length and pitch of leaders. Comparison of relative efficiency and capacity of various furnaces of same grate area but of different amounts and arrangements of heating surfaces. Comparison between hard- and soft-coal furnaces. A study of cold air and recirculation. A standard method of rating furnaces. The effects of modifying the design and installation. Address Director C. R. Richards, Engineering Experiment Station, Urbana, Ill.

*Iowa State College, Engineering Experiment Station E1-20* The Engineering Experiment Station was organized in 1904 and receives an appropriation of \$35,000 per annum. The complete equipment of the Engineering School is available for the Experiment Station. The application of mechanical engineering to agricultural machinery, including tractors, receives considerable attention. Iowa State College, Agriculture and Mechanical Arts, Ames, Iowa. Address Anson Marston, Director.

*Texas Engineering Experiment Station E1-20* The Texas Engineering Experiment Station, College Station, Texas, has issued twenty-two Bulletins, fourteen of them dealing with highway engineering, one with chemistry, one with cotton cultivation, one with purchasing, one with geology, three with homes and one with fuels. Address J. C. Nagle, Director, Texas Engineering Experiment Station, Agricultural and Mechanical College of Texas, College Station, Texas.

## F—BIBLIOGRAPHIES

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file in the offices of the Society.

*Chemistry, General, F1-20* Chemical Warfare. A bibliography of 12 pages prepared by Dr. Clarence J. West of the Arthur D. Little Co., Inc. Address Arthur D. Little, Inc., Cambridge, Mass.

*Chemistry, Organic F2-20* Alcohol. The Production of Alcohol from Sulphate Waste Liquors. A bibliography of 6 pages prepared by Dr. Clarence J. West of the firm of Arthur D. Little, Inc. Address Arthur D. Little, Inc., Cambridge, Mass.

*Electrochemistry F1-20* Electric Furnaces, Design and Construction. Search 2880. A bibliography of 5½ pages. Address A. S. M. E., 29 West 39th St., New York.

*Fuels, Gas, Coal and Coke F1-20* Colloidal Fuels and Low-Temperature Distillation of Coal. A bibliography of 1½ pages. Search 2878. Address A. S. M. E., 29 West 39th St., New York.

*Heat F1-20* Utilization of Waste Heat for Generating Steam. A bibliography of 3 pages. Search 2741. Address A. S. M. E., 29 West 39th St., New York.

*Hydraulics F2-20* Sprinkler Nozzles, by F. W. Greve and W. E. Stanley. A bibliography of 6 references on sewage sprinkler nozzles. Address A. S. M. E., 29 West 39th St., New York.

*Metallurgy and Metallography F2-20* Electric Furnaces. See Electrochemistry F1-20.

*Research F1-20* Industrial Research. A bibliography of 8 pages on a reading list on Industrial Research, prepared by Dr. Clarence J. West and Edward D. Greenman of Arthur D. Little, Inc. Address Arthur D. Little, Inc., Cambridge, Mass.

# Work of the Boiler Code Committee

**T**HE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 273-282, inclusive, as formulated at the meeting of February 26, 1920, and approved by the Council. In accordance with the Committee's previous practice, the names of inquiries have been omitted.

FIG. 3 VERTICAL SINGLE-FLUE BOILER WITH CORRUGATED FIRE BOX

## CASE NO. 273

**Inquiry:** Does Par. 296 of the Boiler Code require that the tee or lever-handled cock be placed immediately under the steam gage where a long connecting pipe is used and the locked-open valve is permitted close to the boiler?

**Reply:** It is the intent of the requirement in Par. 296 that the tee or lever-handled valve shall be located near to the steam gage so that it will be readily evident to any one observing the gage, even though the locked-open valve is used at or near the boiler.

## CASE NO. 274

**Inquiry:** Is it permissible to use upon an h.r.t. boiler with the third return type of setting, an extended nozzle formed of a short length of pipe screwed into flanged fittings at the boiler connection and the other end, in order that it may reach well above the boiler brickwork?

**Reply:** The construction proposed will not meet the Code requirements, where the pipe is over 3 in. pipe size and the working pressure exceeds 100 lb. per sq. in. A double-flanged nozzle riveted to the boiler shell should be provided, one form of

which is illustrated in Case No. 232, or a standard pressed-steel nozzle may be used in lieu of the one illustrated by Case No. 232. If such standard nozzle is used, it should be protected by insulation.

## CASE NO. 275

**Inquiry:** Is autogenous welding permissible for the longitudinal joint of the fire box of a form of vertical boiler as shown in Fig. 3, where the furnace section is, after welding, heated and corrugated by rolls? The corrugations are rolled to a depth of 1½ in. on 8 in. centers, and the weld shows no fracture or distress after either corrugating or flanging.

(In the hands of the Committee)

## CASE NO. 276

**Inquiry:** In the design of a cast-steel water box to be set in the side walls of furnaces and to be subjected to full boiler pressure, is it necessary to apply to the sections containing flat surfaces, the formula in Par. 199 of the Boiler Code, using  $C = 120$ , or is it necessary to use this formula with the value of  $C = 156$ ?

**Reply:** It is the opinion of the Committee that the construction of pressure parts of the type referred to is provided for by Pars. 9 and 247. If the Secretary of the Boiler Code Committee can be notified when the specimen is ready for test, steps will be taken to have a representative of the Committee present.

## CASE NO. 277

**Inquiry:** a An interpretation is requested of the application of Par. 212a of the Boiler Code with reference to any curved stayed surface subject to internal pressure. Does this refer to both the outer and furnace sheets of vertical tubular boilers?

b If under the requirements of Par. 239 of the Boiler Code relative to furnaces under 36 in. in diameter, the design of the furnace does not permit of operation without staying, is there any rule in the Code for the staying in this case, or must the furnace sheets be stayed as flat surfaces, using Table 4 for the pitch?

c Is it the intent of Par. 212c of the Boiler Code that the increased pitch allowed, may be used for the same working pressure and thickness of plate as indicated in Table 4? It is the understanding that Table 4 is based on the formula given in Par. 199.

**Reply:** a The term "curved stayed surface subjected to internal pressure" in Par. 212a of the Code is intended to refer to any surface in a boiler structure that is subjected to pressure on the concave side. It therefore refers only to that part of the outer shell of a vertical tubular boiler which is stayed.

b Where a furnace under 36 in. in diameter requires staying, it should be stayed as a flat surface as provided for in Table 4, except that the pitch may be increased as indicated in Par. 212c.

c It is the intent of Par. 212c that the increased pitch there permitted, may be used for the same steam pressure and thickness of plate as specified in Table 4.

## CASE NO. 278

(In the hands of the Committee)

## CASE NO. 279

(In the hands of the Committee)

## CASE NO. 280

**Inquiry:** a Is it permissible under the requirements of the

Boiler Code to use a blow-off valve of the type used on locomotive boilers, operated by a lever lift, for stationary boilers?

*b* Is it considered safe to use superheated steam of 125 lb. pressure and 125 deg. of superheat, or total nominal temperature of 478 deg., with a piping system having extra-heavy cast-iron fittings and medium-weight cast-iron valves?

*Reply:* *a* It is the opinion of the Committee that the blow-off valves required by Par. 311 for stationary boilers, may be of the lever-lift type, provided they are of extra-heavy construction, and so designed that they may be operated without shock to the boiler.

*b* Attention is called to Par. 12 of the Code which states that cast iron shall not be used for nozzles or flanges attached directly to the boiler for any pressure or temperature, nor for boiler and superheater mountings such as connecting pipes, fittings, valves and their bonnets, for steam temperatures of over 450 deg. Fahr. While the Code only covers the parts therein specifically mentioned, this paragraph clearly indicates the judgment of the Committee as to the safety of the construction in question.

#### CASE No. 281

*Inquiry:* Is it the intent of Par. 306 of the Boiler Code that

every superheater shall be so fitted with a drain that it can actually be completely drained? Many superheaters are fitted with drains which are, however, unable on account of their positions, to completely drain the apparatus.

*Reply:* It is the opinion of the Committee that every superheater should be so fitted with a drain as to substantially free the superheater from water when the drain is opened.

#### CASE No. 282

*Inquiry:* Is it the intent of the Boiler Code Committee that the diameter at the base of the threads on the threaded ends of through rods or braces for h.r.t. boilers, shall be equal to or greater than the nominal diameter of the rod? Fig. 14 and Pars. 208 and 211 would seem to infer that it should be at least equal, but isn't it preferable to make it greater, so that the point of greatest weakness in the rod may not be in the threaded portion where permanent set due to strain would tend toward fracture?

*Reply:* It is the opinion of the Committee that it will be desirable that the threaded ends of through rods or braces for h.r.t. boilers, shall be sufficiently upset so that the minimum diameter at the base of the threads is in excess of the nominal diameter of the rod.

## CORRESPONDENCE

**CONTRIBUTIONS** to the Correspondence Departments of **MECHANICAL ENGINEERING** by members of **The American Society of Mechanical Engineers** are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

### Proposed Symbol for B. T. U.

TO THE EDITOR:

For some fifteen years I have used the following symbol as a substitute for the three letters of B.T.U.:

You will note that the three letters are combined and are speedily produced in two strokes without the use of periods. Having found it very convenient. I am submitting it to you for possible publication in the hope that others interested might find it equally helpful.

R. L. WEBER.

Kansas City, Mo.

### Calculation of Stresses in a Rectangular Plate

TO THE EDITOR:

There are several formulae in the handbooks for the solving of stresses in rectangular plates, but so far as the writer knows, each one of them is either empirical in its nature or has been mathematically derived from an assumption which is admittedly not true, but which, it is hoped, approximates the truth more or less closely. The writer, therefore, starting with such an assumption, presents a method for calculating the stresses in a rectangular plate supported at its four edges and loaded perpendicularly to its surface, and hopes that some light may be thrown upon the subject which will definitely determine whether or not the assumption and the method based upon it are correct.

It is a well-established fact of mechanics that in an ordinary beam the stress at any point, due to the combination of several loads upon the beam, is equal to the algebraic sum of the stresses caused at that point by each of the several loads taken inde-

pendently. The writer assumes that this same method can be used to solve rectangular plates by first finding for a given point the stress, considering the plate as a simple beam supported on only two of its opposite edges, and then finding the stress for the same point, considering the plate as a simple beam supported on its other two opposite edges, and finally by combining these two stresses to obtain the magnitude and direction of the stress in the rectangular plate when supported at all four edges. As these two stresses are at right angles to each other they must be combined vectorially, which makes the resultant stress equal to the square root of the sum of the squares of the two simple beam stresses.

In solving these two simple beams we cannot take the same loading for each simple beam as we have on the rectangular plate itself, because then upon combining the two simple beams, the combined loading would be greater than the loading on the rectangular plate itself. What we must do is to take such loading on each of the two simple beams that the summation of their loading equals the loading on the rectangular plate.

In order to take the simplest possible case, we will consider a square rectangular plate of length  $L$ , uniform thickness  $d$ , with a uniformly distributed load upon its surface of  $w$  lb. per square unit of surface, and with all four of its edges supported freely.

Obviously, as the plate is perfectly symmetrical, we should make the loading on each simple beam half the value of the loading on the rectangular plate, i. e.,  $\frac{1}{2} w$  lb. per square unit of surface. Following this through, we find that the stress at the

center of the square plate is  $\frac{3\sqrt{2}wL^2}{8d^3}$ , and its direction is along the diagonal of the square. The stress at the middle point of each edge is  $\frac{3wL^2}{8d^3}$ , with a direction along the edge itself. The stress

at each of the four corners is zero. The stress for other points in the plate could be found similarly.

An additional assumption is needed for the solving of rectangular plates that are not square, but the writer does not think

it worth while to take up in detail this more complicated case until the assumption for the solving of square plates has been proved. He therefore gives only the result, as follows: Taking the same conditions for the rectangular plate as for the square plate, except that the rectangle has sides of length  $a$  and  $b$ , the stress

$$\text{at the center becomes } \frac{3\alpha a^2 b^2 \sqrt{a^2 + b^2}}{4(t^3(a^2 + b^2))}$$

The writer concludes with the statement that if this method is correct it can be used as the basis of the calculation of such problems as determining the thickness of cylinder heads, steamchest covers, and other problems involving flat plates.

H. W. SIERT.

(Galesburg, Ill.)

## Strength of Thick Hollow Cylinders

TO THE EDITOR:

In the discussion on my paper on Valves and Fittings for High Hydraulic Pressures, presented at the Annual Meeting of the A. S. M. E. in 1918, the point was made that the formula used for the strength of hydraulic pipes and cylinders was difficult to apply, especially when contrasted with the greater simplicity of Barlow's formula. The method which I used was based on the results of experiments by Cook and Roberts, published in London *Engineering*, December 13, 1911, which, after considerable study, I was convinced offered the best basis for design.

Trans. Am. Soc. M.E., vol. 40, page 977.

FIG. 1. STRENGTH OF THICK HOLLOW CYLINDERS

FORMULA:  $t = r \pm \sqrt{P/f(0.6f - p) - r^2}$ , in which  $r = 0.5d$ .

EXAMPLE: Given  $P = 7500$  lb. per sq. in.;  $f = 27,000$  lb. per sq. in.;  $d = 2\frac{1}{2}$  in. Solution: Draw line  $xyz$  from 7500 on  $P$ -scale through 27,000 on  $f$ -scale, cutting  $P/f$ -scale at 0.279; next draw  $xz$  to  $t/d$ -scale, cutting it at 0.183; then draw  $xyz$  to 2.3 on  $d$ -scale, cutting  $t$ -scale at 0.183, which gives required thickness.

FIG. 2. STRENGTH OF THICK HOLLOW CYLINDERS

BARLOW'S FORMULA:  $P/t = t/R$ , or  $P/f = 2t/(d + 2t)$ , in which  $P$  = internal pressure;  $f$  = fiber stress;  $t$  = thickness;  $r$  = outside radius;  $d$  = inside diameter.

EXAMPLE: Given  $P = 7500$  lb. per sq. in.;  $f = 27,000$  lb. per sq. in.;  $d = 2\frac{1}{2}$  in. Solution: Draw line  $xyz$  from 7500 on  $P$ -scale through 27,000 on  $f$ -scale, cutting  $P/f$ -scale at 0.279; next draw  $xz$  to  $t/d$ -scale, cutting it at 0.183; then draw  $xyz$  to 2.3 on  $d$ -scale, cutting  $t$ -scale at 0.183, which gives required thickness.

Recently, having occasion to calculate some piping, I found that I could make a chart, using the principles of the formula given in my paper, by which the strength of almost any cylinder could be obtained without calculation. I am enclosing a print of this chart, and also one for the application of Barlow's formula which I find many designers use. It will be noted that these two charts are the same except for the relation lines between the  $P/f$  and  $t/d$  scales at the right side of the chart. The charts are self-explanatory and will be found time savers and sufficiently accurate for any ordinary case.

Torrington, Conn. WM. W. GAYLORD.

A national association of present and former officers of the Corps of Engineers and civil engineers who have served in any branch of the army—Engineers, Ordnance, or Signal Corps; Infantry, Cavalry or Artillery—is being organized in Washington by a committee appointed by the Chief of Engineers. The objects of this society are to promote the science of military engineering, and to foster the co-operation of all arms and branches of the service, and of civilian engineers in that science. Provisions have been made for an annual meeting, the date of which is to be fixed with reference to that of the American Society of Civil Engineers, in order that members may attend both meetings. The annual dues will not exceed \$5 per year. Further information regarding the society may be secured from Col. G. A. Youngberg, Office of the Chief of Engineers, U. S. Army, Washington, D. C.

# Standard Sizes for Shafting

## Committee of the A.S.M.E. Recommends 14 Sizes of Transmission Shafting and Large Reduction in Number of Sizes of Machinery Shafting

THE desirability of reducing the number of sizes of shafting and in consequence the number of parts of power-transmission equipment that must be carried in stock has long been recognized. It remained for the conditions of the war, however, to bring about definite action in this regard, from the standpoint of the conservation of materials. The activities of the Committee of The American Society of Mechanical Engineers on War Industries Readjustment brought to light the fact that an immense amount of steel is continuously tied up in manufacturers' and dealers' stocks of shafting and that a corresponding amount of cast iron is also held in stock in the form of hangers, bearings, couplings, collars, bushings, pulleys, etc. At the suggestion of the chairman of the Committee on War Industries Readjustment, therefore, a committee was formed to investigate the subject of the standardization of shafting sizes. The personnel of this committee is as follows:

Cloyd M. Chapman, *Chairman* Geo. N. Van Derhoef  
Hunter Morrison Louis W. Williams  
Russell E. Nelles

This Committee was confronted with two distinct but closely related problems, viz., the standardization of the diameters of shafting used for the transmission of power, such as lineshafts, countershafts, etc., and the standardization of the diameters of shafting used by machinery manufacturers in making up their product. The first of these problems seemed to be the simpler of the two. While a large number of sizes of transmission shafting are now listed and stocked, it was believed that a comparatively few of these are in extensive general use. Accordingly, a letter was sent to 36 of the largest manufacturers and dealers in transmission shafting asking for statistics on the consumption of each size of shafting handled by them. Some 20 of the largest concerns in the industry furnished complete statements of their sales over periods of time chosen by themselves. These data were reduced by the committee to a uniform basis of percentages. The amount of each size sold was expressed as a percentage of the total sales, both on a weight basis and on a lineal-foot basis. From these data, plotted in the form of a diagram, it was very evident which of the sizes were popular and generally used and which were more rarely called for. A tentative list of 12 sizes was prepared from this diagram and sent to forty-six other dealers in transmission shafting and shafting supplies from whom twenty replies were received.

In the letters to these firms, the committee expressed the opinion that the custom of using shafting  $\frac{1}{16}$  in. under the unit sizes is so firmly and so nearly universally established in this country, that it would be unwise to attempt to adopt sizes in even inches and fractions as standard. It was pointed out, also, that certain sizes stand out preëminently as "popular sizes" and that others are sold in relatively small quantities. It seemed very feasible to select a series of standard sizes which would meet the popular demand and give a sufficient selection of sizes for general purposes and at the same time reduce the number of sizes now listed by the trade from some 50 or 60 down to 12 or 15.

The response to these letters was hearty and practically unanimous in opinion. The transmission-shafting users and dealers, almost to the last one, approved the plan of standardization and the sizes suggested were very generally approved except that the diameters  $1\frac{1}{16}$  in. and  $2\frac{1}{16}$  in. were in many cases requested to be included. After due consideration the committee decided to include these two sizes in the original list, making the 14 sizes now adopted as standard.

The second problem was a more intricate one. The number of sizes now produced by the rolling mills for use in machinery is very large. Almost every sixty-fourth of every inch up to three inches is drawn. This means excessive equipment at the mills and large stocks in the warehouses. If a reasonable num-

ber of these sizes could be eliminated or classed as "Specials" and a comparatively few sizes selected as standard or stock sizes, a great saving would thus be effected and a valuable service performed.

In order to get the opinions of leading consumers of shafting for machinery purposes, the committee decided to lay the plan before some 225 large consumers of this material and invite their comment upon its desirability or feasibility and their advice as to the size interval between standard diameters which should be considered. It was explained that it was not intended that the adoption of certain sizes as standard should make it impossible to secure any other size required on special order; but that the general elimination of a great number of the sizes now in use and the consequent greatly increased production of the standard sizes could only tend to a reduction of mill costs and capital invested in manufacturers' equipment and in stocks in warehouses. Both of these savings should have a lowering effect upon the price to the consumer and the problem was, therefore, truly one of conservation.

In the case of machinery shafting the users were equally unanimous in their approval of the plan to standardize sizes, but recommendations as to size interval varied greatly. However, these recommendations, in so far as they were definite and specific enough, were tabulated and a diagram constructed showing the relative popularity of the various size increments for each inch of diameter.

With these data accumulated and sifted down to usable form, the committee felt that it was in a position to present its information and preliminary deductions to representatives of other interested organizations. Accordingly, invitations were issued to twelve societies and associations requesting them to consider the proposed lists of standard sizes and to appoint representatives to confer with the committee before its report was finally formulated. The seven organizations listed below responded and the standard sizes which follow have the unanimous approval of these representatives and, as far as can be learned, of their associations.

American Hardware Manufacturers' Association  
American Railway Engineering Association  
American Supply & Machinery Manufacturers' Association  
National Association of Manufacturers of the U. S. A.  
National Association of Purchasing Agents  
National Machine Tool Builders Association  
Southern Supply & Machinery Dealers Association

The committee then considered that it had completed the first part of the work to which it had been assigned, so on January 14 submitted to the Council a progress report in which it recommended the approval and adoption of the following lists of sizes as standard for the Society:

### Transmission Shafting:

15/16 in.; 1-3/16 in.; 1-7/16 in.; 1-11/16 in.; 1-15/16; 2-3/16 in.; 2-7/16 in.; 2-15/16 in.; 3-7/16 in.; 3-15/16 in.; 4-7/16 in.; 4-15/16 in.; 5-7/16 in.; and 5-15/16 in.

### Machinery Shafting:

Size intervals extending to  $2\frac{1}{2}$  in., by sixteenth inches; from  $\frac{3}{4}$  in., to 4 in., inclusive, by eighth inches; from 4 in., to 6 in., by quarter inches.

The Council approved the report and accepted the recommendations.

In the opinion of the committee the adoption of standard sizes of shafting will mean that in the future there will be a gradual elimination of odd sizes from makers' lists and from dealers' stocks, and for new construction only standard sizes would be selected.

Before undertaking the standardization of the shafting formulae and the dimensions of shafting keys and keyways the committee plans to reorganize itself and add to its membership.

# MECHANICAL ENGINEERING

THE JOURNAL OF THE AMERICAN SOCIETY  
OF MECHANICAL ENGINEERS

Published Monthly by the Society at  
29 West Thirty-ninth Street, New York

FRED J. MILLER, *President*

WILLIAM H. WILEY, *Treasurer* CALVIN W. RICE, *Secretary*

## PUBLICATION COMMITTEE:

GEORGE A. ORSBOK, *Chairman* J. W. ROE

H. H. ESSELSTYN GEORGE J. FORAN

RALPH E. FLANDERS

## PUBLICATION STAFF:

LESTER G. FRENCH, *Editor and Manager*

FREDERICK LASK, *Advertising Manager*

WALTER B. SNOW, *Circulation Manager*

136 Federal St., Boston

Yearly subscription \$4.00, single copies 40 cents. Postage to Canada, 50 cents additional; to foreign countries \$1.00 additional.

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

## Editorial Associates on Mechanical Engineering

C. E. Davies, a graduate of Rensselaer Polytechnic Institute, and for several years in production work with the Remington Typewriter Company, Syracuse, N. Y., has joined the staff of MECHANICAL ENGINEERING as one of the Associate Editors. Mr. Davies was in the Ordnance Department at Frankford Arsenal for 15 months during the war, and left the service with the rank of Captain.

E. W. Tree, who has been with the Society during the past year and was formerly an instructor in the Electrical Engineering Department of Brooklyn Polytechnic Institute, has also been appointed an Associate Editor. Of the other members of the Staff, Leon Cammen, for many years Associate Editor, will continue in this capacity and as in the past prepare the Engineering Survey; and C. M. Sames, Associate Editor for four years, will have the direction of the Engineering Index.

## A.S.M.E. to Meet in Convention at St. Louis, May 24 to 27

A tentative program for the Spring Meeting is printed in Section 2 of this number of MECHANICAL ENGINEERING. In connection with it, announcement is made of an opportunity to visit the immense hydroelectric plant at Keokuk, on the Mississippi River, illustrations and description of which appear in this number. Particulars regarding the excursion are contained on page 60 of Part 2, or Society Affairs Section, of this issue.

Papers to be presented include several groups upon certain special subjects, such as aeronautics, the appraisal and valuation of property, and foundry practice. One session will be devoted to scientific papers, and another to miscellaneous papers, mainly on power-plant subjects. The St. Louis Local Committee will have a session of their own, with papers of local interest, principally upon new developments in river transportation, and on industrial housing, a large project for which is under way at St. Louis.

Two papers of unusual interest come from Government sources, one of which will be by Lieut.-Colonel H. W. Miller, Artillery Division, U. S. A., who recently contributed the German Long-Range Gun article to MECHANICAL ENGINEERING. Colonel Miller has investigated heavy artillery abroad and will speak on the formidable German defenses on the coast of Belgium. Lieut. E. R. Jackson, Ordnance Department, U. S. A., Tank, Tractor and Trailer Division, will show moving pictures of the transcontinental trip made by a large number of army trucks, an extended account of which was published in the last number of MECHANICAL ENGINEERING.

The Local Committee has arranged several excursions and social affairs, listed in the tentative program, which are most attractive. Members of the A. S. M. E., and their friends, who can do so, are cordially invited to attend.

## "Conservation Through Engineering"

Past-Secretary of the Interior, Franklin K. Lane, who upon retiring from that office characterized official Washington as "rich in brains and in character, but poorly organized for the task that belongs to it" has given considerable attention to the engineering features of the work of that department. This is evidenced by the frequent and comprehensive references made to engineering work in the last annual report of the Secretary of the Interior, and by the specially-printed extracts of that report which have been published under the title quoted above.

This report deserves the careful attention of all engineers. The recent coal strike and the attention given it by the Interior Department is covered in considerable detail with pertinent questions asked and answered as to the means of conserving coal and meeting future emergencies of this kind. Under the heading, White Coal and Black, the question of water power is briefly treated. Petroleum from the standpoint of its production from oil shale and its use as fuel and generating power is also discussed with a comprehensive summary. It will be recalled that Mr. Lane was especially active with broad plans for soldier settlement legislation,—it was he who first introduced soldier settlement plans. Other phases of the reclamation and development program are covered in an interesting manner. Conservation Through Engineering is a public document known as Bulletin No. 705, and may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at ten cents per copy.

## A University for the Industries as Well as for the People

The University of Michigan, long a source of help and inspiration to the people of its own state, as well as to its many students and friends in other sections, is now arranging for extensive cooperation with the industrial and technical interests of the state along the lines of scientific research.

A new department of Industrial Research is to be organized in connection with the Colleges of Engineering and Architecture. The department will be under the administration of a director, who will be assisted by an administrative committee of the University and by an advisory board composed of men representative of the industries of the state. Investigators and assistants will be assigned to the Research Department as required, and the work in this department will be open to graduate and undergraduate students under suitable conditions. The industry or group of industries having researches undertaken is to pay for these researches, and the University reserves the right to make public at such times and in such ways as it deems best the results of any work done on any problem by the Research Department. The University is to set aside for the miscellaneous expenses of the department a sum of \$10,000 a year, and it is expected that the industries of the state will provide initial funds, in part, at least, for meeting the preliminary expenses incident to the laboratory equipment required for the new undertaking.

This action by the University has followed a report recently made by the Michigan Manufacturers' Association recommending such coöperation. A great deal of credit is also due to the Chicago Engineering Alumni of the University who prepared a report on this subject in 1916 and whose long-sustained efforts to bring the industries into closer relations with the University are now to bear fruit. These Chicago alumni have done a great deal in various directions to advance the cause of research as evidenced by resolutions presented at the last Spring Meeting of The American Society of Mechanical Engineers, largely through their efforts, in which a broad program was outlined for research generally throughout the country, and in which the colleges of the country were an important element.

### Annual Volume of Engineering Index to be Issued May 15

The 1919 annual volume of The Engineering Index will be available about May 15th, the earliest date at which it is possible to complete printing. This publication has been compiled from the monthly issues of The Engineering Index which have been a feature of MECHANICAL ENGINEERING during the year just passed. The items as they appeared from month to month were classified under general headings designating the broad divisions of engineering, but an extended investigation of the merits of different systems of indexing showed that an alphabetical or dictionary arrangement was greatly preferred by the users. Accordingly, in the preparation of the annual this system has been followed. The 12,000 items comprising the index have been entirely rearranged according to this system by a staff of engineers, and while this has entailed many weeks of labor it is believed that the result will fully justify the effort.

### Diesel-Electric Drive for Ships

The Diesel engine has regularly been used in submarines as the propulsive power for driving the propeller when on the surface, and also for charging the storage batteries through a generator, thus providing an electric drive when submerged. In the meantime a method for driving the propeller from a prime mover, through the intermediary of an electric generator and a motor, was developed in this country and first applied in the form of a steam turbine-electric drive such as now used on the U. S. battleships.

The many good features of the electric drive for ships, in combination with steam turbines, have been so fully demonstrated that it was to be expected that the same system would be tried in combination with Diesel engines. The Diesel engine, like the turbine, is capable of extraordinarily high economy, and, like the turbine, it should be operated under the conditions which its constructive features demand, rather than under the conditions imposed by the speed limitations of the propeller.

What is said to be the first trial of a Diesel-electric drive for ships is reported in the current issues of the marine papers as being on the yacht *Elfay*, a schooner of 152 ft. length overall, 30 ft. beam and 313 gross tons capacity. The yacht is driven by a 6-cylinder Winton Diesel oil engine rated at 115 hp., at 425 r.p.m., direct-connected to a 75-kw. Westinghouse generator, which in turn is direct-connected to a 9-kw. exciter. The motor for the propeller is rated at 90 hp., at 360 r.p.m. The entire boat is operated and controlled by electricity, no steam being used or required. All the auxiliaries are electric-driven and all movements are controlled from the bridge without having to signal the engine-room.

The yacht is said to make  $8\frac{1}{2}$  knots on  $7\frac{1}{2}$  gal. of fuel per hour; and since she can carry 2400 gal. of fuel, she is able to run 2000 miles on her propelling equipment alone. Although the *Elfay* is by no means a typical merchant vessel, it is believed that if the new drive proves successful on her it will be extended to purely commercial ships. In fact, consideration is now being given to the application of Diesel-electric power to some of the wooden freight vessels of the Ferris type now offered by the U. S.

Shipping Board, where there is not sufficient headroom in the hold for boilers and engines of the usual type. In an article in *International Marine Engineering* for March, the project is outlined for placing Diesel engines on the main deck of the ship, using as many units as are required for the power to be generated, these engines being of the stationary type, but light enough for marine use.

### Recent Development in American Aeronautics

The aeronautical show held in New York during the second week of March brought out no very startling and novel developments, but it clearly demonstrated that the aeronautical industry in America is developing along sane and conservative lines.

Contrary to statements repeatedly made in the daily press, the aeroplane and aeronautic-engine plants are neither closing their doors nor dismissing their engineering personnel. On the contrary, they are doing fine work and are gradually placing the industry in the position to which it is entitled in view of the fact that the aeroplane was conceived in this country and made to fly for the first time as a result of the genius and perseverance of American engineers.

In this connection attention may be called to an important publication issued by the director of Air Service, Washington, D. C., namely, a Report on First Transcontinental Reliability and Endurance Test, conducted by the Air Service, U. S. A., in October, 1919. The official conclusions arrived at on the basis of a very careful analysis of all that happened are of unusual interest.

As regards motors, it is stated that on the whole the performance of the Liberty motor can be considered quite satisfactory although one is constrained, after very careful consideration of all the circumstances, to arrive at the conclusion that the Liberty motor cannot run full out for more than 40 hours, though with careful nursing to avoid excessive vibration it will run over 100 hours without overhaul.

A Hispano-Suiza motor should act well and the test showed that with some care the high-compression Hispano-Suiza motor will stand up against fearful strain.

It is not entirely pleasant to find that on the whole the German Mercedes 160-hp. low-compression motor gave a performance which the official report describes as "wonderful." No spare parts were needed and only a few minor adjustments to the magnetos, jets and plug points were made.

As regards planes, the test has shown conclusively that the DH-4 is a very good machine. On the other hand, the SE-5A made a remarkable showing in the test. Although as a single-seater plane it was not designed for the long, continuous flights of a trans-continental trip, it gave less trouble than the DH-4. The Martin bomber, which was the only type of multi-engine machine entered, showed an extremely fine performance and despite its great load kept up with the lighter craft.

In this flight there were several fatalities, the causes of which are carefully analyzed in the report. In general it would appear that while extensive precautions are taken in a test of this nature, it is nevertheless practically impossible to avoid accidents. One of the rules of the test stated that aeroplanes entered must be capable of a speed of over 100 m.p.h. These aeroplanes designed for war purposes are not as safe as the less speedy craft which would be flown for commercial purposes. It is another question whether such a rule should have been made for such a test, as obviously even in war times high-speed aeroplanes would hardly be used for transcontinental flying, except under very unusual circumstances.

The test strongly accentuated the importance of the pilot and demonstrated clearly that he is not merely an aerial chauffeur.

Considering the show and the report of the transcontinental flight, together with the high-altitude flight of Captain Schroeder (of which more is said elsewhere in this issue) as the three outstanding events of March, 1919, one can hardly help coming to the conclusion that aeronautics is quite alive in this country and very gratifying results are being obtained.

## The Engineer's Attitude on Military Legislation

Despite the fact that Congress has failed to enact legislation dealing with the subject of military training, and that public opinion seems at least to be divided on the question, the engineers through Engineering Council have gone on record as favoring a sound and effective development of both army and navy. This recommendation of Engineering Council comes through its Military Affairs Committee which was appointed in December, 1919, to consider the relation of engineers to the future military activities of the United States. Col. William B. Parsons is chairman of the committee, which is composed of both civilians and ex-officers of all branches of the service. The committee's recommendations to Engineering Council which were unanimously adopted by the executive committee of that body are in part as stated in the following paragraphs:

We believe it of vital national importance that sound military legislation should be enacted during the present session of Congress. Effective provision for national defense with an adequate trained army and navy sufficient to discharge our national and international obligations is essential to security and stability, which must be present if our country is to go forward in constructive activity and achieve its possibilities as a nation.

The careful selection and training of personnel and their assignment, when reservists, to organized reserve units are vitally important to the efficiency of the technical services of the army and navy, and therefore essential to the proper preparedness of the individuals of the engineering and allied professions and trades for the discharge of their constitutional obligations in national military service.

The full utilization of specially and technically qualified men and specialized industries has proved impossible where an organization was built up only after war had become imminent or had been declared.

We believe national security and stability can be assured only by application of the foregoing principles, in particular the principle of universal military training and the creation of organized reserves, above all in the technical branches. We, therefore, recommend to Engineering Council that the President, and Vice-President of the United States, the Secretary of War, the Secretary of the Navy, the Speaker of the House and the Chairmen and Members of the Military and Naval Committees of the Senate and the House be urged to incorporate the foregoing principles into any bills passed by either body for army or navy organization, and particularly the principle of universal training.

## The Future Engineer—A Man of Affairs

Engineering started as an art; then it developed into a science. Later it was realized that the engineering of men was as important as the engineering of things and the science of management came into being. Finally, the management of affairs, of men and things taken together collectively, is receiving a great deal of consideration and there is a general movement in the technical schools and colleges toward the teaching of business administration to engineering students.

How general this movement is has been shown in a recent report of the U. S. Commissioner of Education based on the replies to letters sent out to a number of the larger colleges and universities requesting "a statement of present practice and any change contemplated in courses of study in engineering and commerce." Fifty-five replies were received, a study of which brings out some interesting facts.

Approximately a third of the replies received came from colleges or universities which offer subjects in economics and business administration in connection with their engineering courses. In general the curricula provide business training in greater or lesser amounts for engineers who expect to enter positions concerned with the management or administration of manufacturing, construction, and transportation enterprises, which demand a

knowledge of business as well as of scientific and engineering principles.

There are several institutions in which the combined business and engineering course is already well developed. For over 20 years Stevens Institute of Technology has given its students instruction in the commercial or business side of engineering. Dartmouth College has offered for four years a course in engineering management. A unique feature of this course is the large requirement in outside reading covering thirty or more books on the subject. The University of North Dakota has offered for three years a course in general engineering, providing about 60 per cent of the work along fundamental subjects in sciences, mathematics and technical engineering, and about 40 per cent in subjects relating to both business and engineering careers.

Massachusetts Institute of Technology gives a course in engineering administration which combines instruction in general engineering studies and in the methods, economics and law of business. The course includes (1) the instruction common to all courses, in literature, language, and history, and in chemistry, physics and mathematics; (2) a choice of engineering studies classified under three options: civil engineering, mechanical and electrical engineering, chemical engineering; and (3) a selected group of subjects in business and economics.

Other colleges which do not cover as much ground in their prescribed course, offer these subjects as electives or, in a few cases, in a special fifth-year course devoted to business administration.

There is only one institution reported in which no course is offered in either commercial or industrial engineering. A few commercial schools include engineering subjects in their courses.

The balance of the reports come from institutions which although they do not now offer a combined course, nevertheless are in favor of doing so as soon as they feel that the demand is great enough. Some of them are now at work on new engineering curricula covering a four, five, or six-year combined course. Columbia University, for instance, plans to have in the near future a course in manufacturing and industrial engineering, and Tulane University, New Orleans, now has under consideration a revision of its engineering curriculum to provide proper business training for engineers.

## Scientific American Supplement Now Issued as a Monthly

The *Scientific American Supplement*, edited by A. Russell Bond, is now issued as the *Scientific American Monthly* and has been greatly broadened in scope. Besides containing important announcements of distinguished technologists appearing in foreign as well as domestic publications, it furnishes translations of the complete texts of significant articles in European books, etc., and has several departments to which various organizations contribute. The National Research Council and the Bureau of Standards each supply material for a department, and a similar section is to be edited by the U. S. Bureau of Mines. The American Society of Mechanical Engineers furnishes regularly a review of important articles in the field of mechanical engineering and a similar service covering the field of mining and metallurgy is being rendered by the American Institute of Mining and Metallurgical Engineers. Reviews are also being given in the fields of electrical engineering and industrial chemistry. The journal is unique in that it carries no advertising, all the pages being text pages. While it is realized that the rapidly rising cost of paper and printing may make it impossible to issue a publication with 96 pages of text, such as this journal contains, from the income received solely from subscriptions, the attempt is nevertheless being made to conduct the journal on this plan.

The *Scientific American Supplement* was founded in 1876 at a time when there was aroused by the Centennial Exposition a great public interest in science. It was established to meet the growing demand for information of a higher technical character than could properly be published in the more popular *Scientific American*.

# Major Schroeder's Record Altitude Flight

## Notes on Major Schroeder's Accomplishment—Technical Difficulties Encountered—Military Value and Commercial Uses of Supercharger

On February 27, Major R. W. Schroeder, chief test pilot of McCook Field, Dayton, Ohio, drove an aeroplane to a higher altitude than has ever before been reached. Official figures show that an altitude of 36,020 ft. was attained and that the official record of 30,300 ft. reached by Rolland Rholls on July 30, 1919, and the unofficial record of 33,137 ft. credited to Adjutant Casale, the French pilot, were broken.

The public is familiar with the story of how Major Schroeder set out to reach the altitude of 40,000 ft.; of his battle against a temperature of 67 deg. below zero and a wind of 100 m.p.h.; of how his oxygen gave out; of his fall of five miles; and of his miraculous landing at McCook Field. Further information regarding the flight, prepared for MECHANICAL ENGINEERING by Col. Thurman H. Bane, Commanding Officer of McCook Field and released by the Air Service, is given below.—EDITOR.

MAJOR SCHROEDER'S successful altitude flight was the result of a long series of important tests in engineering development by the Engineering Division of Air Service, U. S. A. This series of tests has disclosed problem after problem which had to be overcome in some manner before further advances could be made. Some of these troubles were:

- a Obtaining a suitable propeller
- b Keeping the mixture ratio of the carburetor constant throughout a wide range of altitude and therefore varying the differences in proportion between the throat of the carburetor and the atmosphere surrounding it
- c Delivering fuel to the carburetor against its varying pressure
- d Cooling at high altitude and raising the boiling point of the water
- e Providing a drain valve to let the water out of the radiator at high altitude in case the engine should stop, so that the engine and cooling system would not be mined by the water freezing; and further, of so arranging the valve that it would not itself freeze and thus become inoperative
- f Securing goggles which would not freeze over in the intense cold at great heights; (such goggles were invented and designed by Major Schroeder)
- g Developing a special instrument to show the pilot how to handle his exhaust bypass gates, or, in other words, how to control the supercharger pressure in his carburetors without the need of making any calculations.

The Engineering Division has been most fortunate in having Major Schroeder to pilot the airplane throughout the preliminary supercharger development tests which were made, because, in addition to being a surpassingly good pilot, he is an excellent engine mechanic and is one of the few pilots who can really sit in an airplane and know what an engine is doing and what it needs. In this way he has helped the development immensely.

Considerable trouble has always been encountered from preignition when running with a supercharger, due to the fact that the air delivered to the carburetor is at very high temperature. Future designs of superchargers will provide additional intercooling between the compressor and the carburetors. The fuel-feed system, prior to Major Schroeder's flight, had operated quite satisfactorily, but in spite of this fact it was necessary for Major Schroeder to close the vents in his gasoline tanks and pump some pressure in them with a hand air pump in order to help the fuel pumps deliver the fuel at the extreme altitudes.

To reduce the preignition which it was expected would be encountered on this flight, a specially prepared fuel was provided by Mr. Thomas Midgeley, Jr., who has been developing "antiknock" fuels for Mr. Charles F. Kettering, Mem. Am. Soc. M. E. This fuel proved to be of great assistance in this flight as it caused the motor to run much more smoothly than it would otherwise have done.

The supercharger used by Major Schroeder was the old original General Electric supercharger designed by Dr. Sanford A. Moss, Mem. Am. Soc. M. E., and originally tested on Pike's Peak in 1918; and it is not surprising, therefore, that no good means had been provided for blowing off the exhaust gases which issue from the turbine. The exhaust gas has bothered the pilot to a certain extent, due to the fact that it sweeps past his face. No way has been found to date to entirely carry the exhaust clear of the occupants of the machine. On this record flight it seems that the gases expanded more rapidly as they issued from the turbine in the thin air at great altitude and that they swept past the pilot's face in even larger volume. Judging from the doctor's report, it seems that the carbon-monoxide poisoning gave Schroeder more trouble than the lack of oxygen.

In military work an automatic oxygen-feed apparatus is provided for the pilot which regulates the amount of oxygen in proportion to altitude so that it is not necessary for him to think of making any adjustments. Major Schroeder had been in the habit of using a simple rubber tube extending from the neck of the oxygen flask to his mask in such a manner that he could adjust the flow by hand, as he has often had trouble with the oxygen pipe freezing up and flow stopping at high altitudes. On his record flight he knew he would be up for a long time, and he desired to use the automatic apparatus as long as he could. He believed it would work to about 29,000 ft., and therefore took one bottle of oxygen, connected through the automatic oxygen feed and one connected direct. However he found that the automatic apparatus did not work at all and he therefore had to start using his emergency bottle at about 18,000 ft., and realized that it might run short, although he thought it would last long enough for him to accomplish his record. Nevertheless, due probably to the large amount of exhaust gas he was breathing, Major Schroeder had to use an excess amount of oxygen, which, of course, resulted in his reaching the end of his supply sooner than he expected.

It is noteworthy that the instrument which shows the pilot what pressure his supercharger is delivering to the carburetor showed a pressure something close to that of sea level, even when he was at the highest point of the flight. The operation of the supercharger was excellent throughout the flight and it was found to be in good condition afterward.

Major Schroeder states that he actually reached warmer temperature at the top of his climb. The coldest temperature record was about -67 deg. Fahr. and two or three thousand feet higher, at the top of his climb, the temperature was 4 deg. higher. He encountered the usual strong west wind which he has in every case encountered at altitudes above 25,000 ft. He believes the velocity of this wind to be close to 175 m.p.h., judging by the rate at which it drifted his machine eastward, even though he was headed west and climbing at an extraordinarily high air speed due to the use of the supercharger. It is to be regretted that figures on these speeds cannot be given for publication.

It is an interesting fact that after a certain low temperature is reached the exhaust gases issuing from the engine become snow white from the freezing of the vapor in them, and from that time on long, white clouds formed by this exhaust are visible from the ground on a clear day such as the one on which Major Schroeder's flight was made. This results in ice forming on all the wires and struts coming in contact with the stream of the exhaust.

When Major Schroeder's oxygen supply finally failed, he raised his goggles in order to see more clearly in his endeavor to "coax" some more oxygen from one or the other of his tanks, and at this moment unconsciousness suddenly overtook him—but not before he reached for his switch and put the machine into a spiral. He intended to make one steep spiral which would bring him down to about 20,000 ft. above the ground, where he expected to

recover; but, although he believed after his fall that he had succeeded in doing this, as a matter of fact the plane fell into a "shot pigeon" down to about 3000 ft. above the ground, where Schroeder regained consciousness, "righted" the plane and, although he was still semi-conscious and could scarcely see at all due to the chilling of his eyes, had the presence of mind to open the vents in his gasoline tanks so that the engine would continue to get fuel and run. It happened that he succeeded in getting only one switch instead of two which are present in all Liberty ignition systems, therefore his engine had been running practically wide open throughout the fall. This kept the water from freezing in the cooling system and gave him the use of the engine after his recovery from the fall.

The daily papers have given the details of his marvelous landing in spite of his almost total blindness, so nothing will be said here about that; however, it is of interest to note that the gasoline tanks which probably had a plus pressure of several pounds in relation to the surrounding atmosphere at the top of the climb had collapsed,—that is, three out of four of them had collapsed, one of them almost totally, due to the fact that at the bottom of the fall conditions had changed so that there was a minus pressure inside of several pounds. This is why it was necessary for Major Schroeder to open the vents in the tanks in order to be able to deliver fuel to the engine to get to a suitable place to land.

The military value of the supercharger will be very great. It will greatly increase the speed of airplanes at high altitudes and enable them to go much faster than they can near the ground. It will be useful for photography at extremely high altitudes, because the photographer will not be hampered by attack if the plane goes high enough. An airplane with supercharged engine will be valuable to carry dispatches or a high-ranking officer over great distances in a very short time. Superchargers, when applied to heavy bombers, will enable this type of machine to reach a ceiling well above enemy anti-aircraft gun fire, and in fighting planes superchargers will greatly increase speed and climb.

Commercial use of superchargers will be to enable heavy passenger- or express-carrying airplanes to climb over the highest mountains or over thunderstorms with the use of comparatively low-powered and low-priced engines; without the supercharger, very large engines would have to be installed in order to have sufficient power to sustain the airplane at high altitudes. This is largely unnecessary if superchargers are used. It is felt that passenger-carrying airplanes can be provided with a supercharger and an airtight cabin for the passengers so that the supercharger can keep the air in this cabin at a density and temperature which will make it practically comfortable for all passengers, and at the same time the airplane can fly at extreme altitudes at very much greater speeds; and speed, after all, is one of the chief advantages of air travel over other kinds.

### James Waring See

James Waring See, a charter member of the A. S. M. E. and a widely known engineer, died at his home in Hamilton, Ohio, on January 31, 1920. Mr. See was better known to the readers of mechanical journals as "Chordal," a pen name used by him for much of his writing. About 1880 he began a series of articles in the *American Machinist* under the title of "Extracts from Chordal's Letters." These articles were of the shop by a shop man and it would be difficult for a person of the present generation to understand the deep impression which they made on the mechanical men of the country and the widespread interest which they created.

Mr. See was born in New York City on May 19, 1850. He received his earliest education in a country school at Rutland, N. Y., though he later attended school at St. Louis, Arcadia and Springfield, all in Missouri.

At the outbreak of the Civil War Mr. See was employed in the Springfield military hospital as an assistant in the dispensary and in the operating ward. After the battle of Carthage he was made telegraph messenger to the Federal forces in and

around Springfield. Upon the ending of hostilities Mr. See served an apprenticeship as machinist at the Springfield Iron Works and it was there he laid the foundation for his future career. At the completion of his apprenticeship he found employment in various shops located from St. Louis to Yankton, S. D., eventually settling at Omaha, Neb., where he started a shop of his own.

The story is told of him that being disappointed in a lathe he bought from the Niles Tools Works he wrote to that firm to the effect that if he could not design a better lathe he would eat it. Alexander Gordon, head of the Niles works, testily replied that if he was able to design a better lathe than the one in question, he wished he would come to Hamilton and do it.

Long after Mr. Gordon had forgotten the incident there appeared in his office a tall, lanky individual who said with a drawl, "My name is See and I came up here to design that

JAMES WARING SEE

lathe for you." He was put off with one excuse after another until in disgust he appropriated an empty drawing board and did design a lathe that made Mr. Gordon sit up and take notice.

He was at once employed by the Niles Works, filling positions as foreman, chief draftsman and chief engineer, respectively. In 1876 Mr. See opened an office in Hamilton, Ohio, as a consulting mechanical engineer and his keen insight into mechanical matters soon brought him a wide practice in connection with some of the largest machine establishments in the United States and Europe.

With the invention of the telephone, Mr. See became greatly interested in its practical workings and was the inventor of several valuable devices connected with central-station apparatus. In recognition of his work he was made an honorary member of the Telephone Exchange Association. For a time he was editor of the *Telephone Exchange Reporter*. He built the first telephone line in Hamilton. Also in connection with Alexander Gordon and James K. Cullen, he built an electric-light plant at the Niles Tool Works, the first in Hamilton.

As Mr. See's business increased, he became a patent attorney and as such developed an enviable reputation as an expert in patent litigation, and was called on to give expert testimony in more than three hundred cases.

By appointment of Governor Campbell, Mr. See acted as one of the commissioners for Ohio to the World's Fair held at Chicago in 1893.

# Government Activities in Engineering

*Notes Contributed by The National Service Department of Engineering Council<sup>1</sup>*

## Agreement Expected on Water Power Bill

As stated in MECHANICAL ENGINEERING for February the Water Power Bill has been in the hands of a committee composed of members from both the House and Senate. This was for the purpose of settling on points of difference, and while it was expected that not more than two weeks would be occupied in getting the bill through this Joint Conference Committee, nevertheless on March 9th, when the committee adjourned for a period of two weeks, there still existed two important points of difference. This adjournment was taken to await the return to Washington of Representative Taylor of Colorado and to permit Senators Jones and Smoot to devote some time to the Merchant Marine and Executive Bills, both of which are now pending.

These differences pertain to license charge and recovery and the proposal to have an army engineer as an executive secretary. The strong opposition to this latter plan will probably result in the placing of a civilian in that office with the authority to have an engineer officer detailed to assist in the work. Those in immediate touch with the status of the Water Power Bill regard the situation as very satisfactory and it is anticipated that a committee agreement may be shortly expected. The power project for Great Falls on the Potomac River, which carries an appropriation of \$25,000,000 and which was placed in the bill as a rider by the Senate, was eliminated in the conference. No further details are at present available concerning the other items of the bill.

## New Board of Surveys and Maps Meets to Perfect Organization

The various developments leading to the creation of a new Board of Surveys and Maps which will coordinate the many map making agencies of the Government were presented in considerable detail in MECHANICAL ENGINEERING for February (p. 134). Since then the members of the Board have met with representatives of non-federal organizations for the purpose of determining the policy of the new Board and the manner in which it shall function. This meeting, held on March 9th, was called by the chairman of the Board, O. C. Merrill, Chief Engineer of the Forest Service, Department of Agriculture.

The report of the committee of representatives of the non-federal organizations was presented by M. O. Leighton of Engineering Council, who stated that while efficiency and economy in centralized mapping operations was most commendable, there might be certain occasions when it would be more advantageous for a particular department to do its own mapping. The consideration of the Board in such cases would have to be in a large degree judicial and representatives of the interested department should be disqualified from participating in decisions affecting that department. It was further suggested that a plan should be adopted by which cooperating non-federal agencies could have a voice in the determination of the manner and the place of disbursement of their contributed funds.

The report of this non-federal committee also commented upon the following special features of the conference report: the preparation of skeleton maps of various scales; the methods of distribution as affected by the size of editions, costs, etc.; and the preparation of maps suitable for educational institutions. The need of a general topographic map of the United States and the means by which its preparation may be expedited was covered from the highway, railroad, and military standpoints by governmental and military officers.

## The Patent Bill

Due much to the efforts of Edwin J. Prindle and his colleagues, the Nolan Patent Bill (H. R. 11984) was put on the House calendar for March 5th, and was passed on the same date. Mr. Prindle is chairman of the Patent Committees of both Engineering Council and National Research Council. It will be recalled that extensive hearings were held before the House Patents Committee so that the case presented to the Rules Committee consisted in urging immediate consideration of the Bill.

About sixty engineers, members of the Founder Societies or representatives of organizations using the Patent Office, supported Mr. Prindle. When the hearing was over, the chairman of the Rules Committee told these men that it had been the most satisfactory hearing held by his committee in over ten years and that the thorough disinterested manner in which the engineers had presented their case assured early action in the House. This assertion was borne out when the House passed the bill a few days later. The bill is now before the Senate Patents Committee who intend to hold short hearings.

## Administering the New Land Leasing Law

The provisions of the Land Leasing Bill, to which reference was made in the last issue (p. 200), went into effect when the President signed it on February 26th. Its administration was handed over to the Interior Department, and to correct the misunderstandings that have arisen in connection with this new law, that department immediately prepared a set of regulations which have now been approved by the Secretary of Interior and are available for distribution.

Inquiries received indicate that many had gained the impression that leases on proven oil lands of great value were to be had merely by the filing out of an application prior to anyone else. The regulations point out that this is not the case, because proven oil lands of the Government are largely covered by claims of various kinds that have been in litigation for some time and which must be submitted for adjustment within six months. Until such claims are acted upon none of the lands can be leased and then only to the extent to which such claims are rejected. Further, if the Government grants a lease for their oil or coal land, except under the relief sections or as the result of a permit, it will only be by competitive bidding of which ample notice will be given to the public.

The only part of the act which is self-operative and not subject to the regulations of the Department is the section which provides for securing a preference right for oil prospecting permit by posting a notice on the ground. This applies only to lands not in the geologic structure of a producing oil field.

## Government to Develop Inventions

In order that the public, the industries, and the various departments of the government may obtain the full benefit of scientific inventions and patents of departmental employees, a bill has been introduced by the Senate Committee on Patents, proposing to give the Federal Trade Commission authority to arrange for the development of useful inventions, patents, and patent rights in the broadest way. This procedure is to be under such regulations as the President shall prescribe.

The Commission is authorized to collect fees and royalties for licensing the inventions, patents, and patent rights in such amounts as the President may direct and to deposit these in the United States Treasury; the necessary percentages however may be reserved for the remuneration of the inventors of meritorious ideas. The appropriations of Governmental departments are made available for the payment of fees charged in connection with the granting of patents under this Act.

<sup>1</sup> Engineering Council is an organization of national technical societies created to consider matters of common concern to engineers as well as those of public welfare in which the profession is interested. The headquarters of Engineering Council are located in the Engineering Societies Building, 29 West 39th Street, New York City. The Council also maintains a Washington office with M. O. Leighton, chairman of the National Service Department, in charge. This office is in the McClatchien Building, 10th and G Streets, Washington, D. C. The officers of Engineering Council are: J. Parke Channing, Chairman; Alfred D. Flinn, Secretary.

# NEWS OF THE ENGINEERING SOCIETIES

Meetings of The American Institute of Mining and Metallurgical Engineers, the American Institute of Electrical Engineers and the Engineering Society of Western Massachusetts

## American Institute of Mining and Metallurgical Engineers

The annual meeting of the American Institute of Mining and Metallurgical Engineers was held in New York, February 16 to 20. The retiring president, Horace V. Winchell, outlined the civic activities of the Institute for the year. The new president, Herbert C. Hoover, an abstract of whose address was published on p. 194 of the March issue of MECHANICAL ENGINEERING, spoke on the national problems in which engineers are directly concerned.

The leading technical feature was a conference of coal operators from all over the country, who assembled to discuss the stabilization of the coal industry. At the opening of the conference, President Hoover, at whose suggestion it was called, outlined a program of study and work for the Institute and a constructive plan for the better working of the bituminous coal industry. Dr. Van H. Manning, Director of the Bureau of Mines, talked on Problems of the Coal Industry. Dr. George Otis Smith, Director of the Geological Survey, in Fluctuation of Production of Coal—Its Causes and Effects, presented a statistical analysis of the rate of output over a period of years, indicating the relative effect of shortage of transportation, shortage of labor, lack of market and other factors in producing intermittency in the operation of coal mines. H. H. Stock, professor of mining at the University of Illinois, discussed the Storage of Bituminous Coal and Its Possibilities of Stabilization. Transportation as a Factor in Irregularity of Coal Mine Operations, by S. L. Yerkes, vice-president, Grider Coal Fields Co., Birmingham, Ala., contained exact data as to the effect transportation facilities have on coal production, use of cars for storage, effect of more equipment, effect of lower rates in spring and summer, reduction of cross hauling, and long hauls by railroads of their own coal.

Numerous papers of scientific interest were presented at the technical sessions on Iron and Steel, Non-Ferrous Metallurgy, Milling and Smelting, Oil and Coal, and Industrial Organization. P. W. Bridgman described an experiment in one-piece gun construction. During the war, the Navy undertook the construction of an experimental gun embodying features designed to lessen the cost and time of production. It was demonstrated by actual construction and firing tests that a gun could be made from a single forging, producing the required distribution of internal stresses by a preliminary application of hydrostatic pressure so high as to strain the material considerably beyond its yield point. The procedure was to start with a single forging of approximately the dimensions of the finished gun, subjected to internal pressure in one or more stages, depending on the external shape, high enough to stress the metal permanently and thus to raise the elastic limit by producing compression in the inside layers and tension in the outside layers. The technique of controlling the pressures required, which were of the order of 100,000 lb. per sq. in., rested chiefly in employing a packing which automatically became tighter at higher pressures.

Tensile Properties of Boiler Plate at Elevated Temperatures was presented by H. J. French. At the request of a committee of the Engineering Division, National Research Council, a study was undertaken of the properties of boiler plate at various temperatures up to about 900 deg. Fahr. Tests were made of  $\frac{1}{2}$ -in. plates of firebox and marine grades. The test specimen was heated by means of an electric tube furnace, two spiral resistors in series being used. In both grades of plate, increase in temperature from 70 to 870 deg. Fahr. was accompanied by distinct changes in strength and ductility. The tensile strength at first decreased a few thousand pounds per sq. in., reaching a minimum at about 200 deg. Fahr. This was followed by an increase up to about 550 deg. Fahr., where the tensile strength reached a maximum about 10 per cent greater than the normal room temperature, after which an-

other and final decrease occurred. The percentage elongation in 2 in. decreased rather slowly up to about 200 deg. Fahr., after which it dropped more rapidly, until a minimum was reached at about 470 deg. Fahr. The reduction in area had a minimum at a slightly higher temperature than the elongation. The proportional limit at first increased slightly and showed a maximum in the neighborhood of 400 deg. Fahr. for the firebox plate and the highest values between 200 and 300 deg. for the marine plate.

Of striking importance were also the following: Intercrystalline Brittleness of Lead, by Henry S. Rawdon; Blast-Furnace Flue Dust, by R. W. H. Atcherson; Critical Ranges of Some Commercial Nickel Steels, by Howard Scott; the Coefficient of Expansion of Alloy Steels, by John A. Mathews; Physical Changes in Iron and Steel Below the Therman Critical Range, by Zay Jeffries.

## The American Institute of Electrical Engineers

The eighth midwinter convention of the American Institute of Electrical Engineers was held in New York from February 18 to 20. A feature of uncommon interest was a symposium on super-power plants and transmission for the Northeast seaboard zone. W. S. Murray, consulting engineer, New York City, explained that the super-power plan provided a means by which a present estimated machine capacity of 17,000,000 hp. in a region between Boston and Washington and inland from the coast 100 to 150 miles, now operating with a load factor not exceeding 15 per cent, could be lifted to a load factor of more than 50 per cent and possibly 60 per cent, and a means by which, conservatively speaking, one ton of coal would do the work of two or three. The railroads within the above zone and those carrying coal into that zone would thereby be relieved of transporting one-half the amount of coal required for power and lighting purposes. That is, the value of machine capacity from a utilization standpoint would be increased from threefold to fourfold and coal resources for the purposes named be conserved twofold. It has been estimated that a saving of \$300,000,000 a year would result from the establishment of this super-power system. In one of the other contributions it was pointed out that generating stations of from 200,000-kw. to 300,000-kw. capacity, employing generating units of from 50,000-kw. to 75,000-kw. capacity, would involve no difficulties of design, construction or operation, and that from such stations a steam consumption rate of 10 lb. per kw-hr. or less and a total station rate of less than  $1\frac{1}{2}$  lb. of good quality coal per kw-hr. output should be obtained. Hope was expressed that a bill appropriating money for this national need would be presented before Congress by July 1, otherwise the plan would have to be financed by backing it with Government bonds or interstate or private capital.

The Measurement of Projectile Velocities, by Paul E. Klopsteg, physicist, Leeds and Northrup Co., and Major Alfred L. Loomis, Ordnance Department, was the title of a paper discussing the requirements imposed by proving-ground practice upon a chronograph intended for general ammunition testing. The number of Boulangé instruments in possession of the Ordnance Department was entirely insufficient for testing the immense quantities of ammunition contracted for by the Government during the war, and a new type of instrument was accordingly developed and adopted as standard ordnance chronograph, which was designated "Aberdeen chronograph." It is an assembly of standard parts with a few necessary special ones and rapid production was thereby made possible. Many comparative tests as to accuracy were made during the process of development, and invariably the average dispersion with the Boulangé chronograph was found to be from two to four times as great as with the Aberdeen. In routine firing, the three Aberdeen chronographs tested agreed within one or two feet per second on a velocity of 1700 ft. per sec., and only rarely

did the maximum dispersion at this value become as great as 5 ft. per sec.

The economic and sociological aspects of daylight saving were discussed by Preston S. Millar, who stated that this wartime measure had reduced the total output of certain central stations and of one gas company by about 3 per cent during the seven summer months, reduction in output for lighting alone having averaged 8 per cent. Applying these data to the country as a whole, Mr. Millar estimated an annual saving by the public of \$19,250,000 in expenditure for artificial light and a reduction of about 495,000 tons per annum in consumption of coal. On the other hand, he estimated the economic losses resulting in consequence of interfering with agriculture, dairying and truck gardening at over \$1,000,000,000. He therefore concluded that the very obvious solution of the problem appeared to lie in diversification of hours of industry. Since advancement of clocks, while serving the interests of one part of the population, has proved so disadvantageous to another part as to compel return to correct time, it seemed obvious, Mr. Millar pointed out, that those who benefit by advanced time in summer should adjust their habits as desired without disturbing the practice of the remainder of the population.

Participation of engineers in public affairs was urged by President Townley in his address. A sub-committee of the Standards Committee of the Institute submitted a proposal to standardize symbols for use in electrical diagrams, and offered for criticism and approval a tentative list of the more fundamental symbols. A dinner-dance at Hotel Astor constituted the social function of the convention.

### Engineering Society of Western Massachusetts

The February meeting of the Engineering Society of Western Massachusetts was held on February 24 at the High School of Commerce Auditorium, State Street, Springfield, Mass. Mr. W. E. Hodge, who is deputy in charge of street lighting in the city of Springfield, spoke on Street Lighting as an Engineering Problem, and Mr. John L. Harper, vice-president and chief engineer of the Niagara Falls Power Co., spoke on Niagara Falls Power Developments. Both lectures were illustrated by slides.

### Government Issues Special Ruling on Reinstatement of War Risk Insurance

Under a new and very liberal ruling, of far-reaching importance to millions of former service men, War Risk (term) Insurance, regardless of how long it may have been lapsed or canceled, and regardless of how long the former service man may have been discharged, may be reinstated any time before July 1, 1920.

The only conditions to be met are: (1) The payment of two monthly premiums on the amount of insurance to be reinstated; and (2) The applicant must be in as good health as at the date of discharge, or at the expiration of the grace period, whichever is the later date.

The new ruling is the most important liberalization of War Risk Insurance since the passage of the Sweet bill, and is designed for the special benefit of service men who failed to reinstate their insurance prior to the new law, and who have been discharged for more than 18 months.

Ex-service men may still reinstate their lapsed term insurance at any time within 18 months following the month of discharge by complying with the same conditions. Within three months following the month of discharge reinstatement may be made by simply remitting two months' premiums without a formal application or statement as to health.

Reinstatement may also be made after 18 months following discharge, as follows: If the insurance has not been lapsed longer than three months by complying with the conditions outlined above. From the fourth to the eleventh month, inclusive, after lapse, by complying with the same conditions, and in addition submitting a formal report of examination made by a reputable physician substantiating the statement of health to the satisfaction of the Director of the Bureau.

War Risk (term) Insurance may be converted into United States Government Life Insurance, now or at any time within five years after the formal termination of the war by proclamation of the President, and such Life Insurance, including Ordinary Life, Twenty Payment Life, Thirty Payment Life, Twenty Year Endowment, Thirty Year Endowment, and Endowment at Age of 62, may now be paid in a lump sum at death, if such method of payment is designated by the insured.

### Annual Report of the A.I.M.E.

In the report of the president of the American Institute of Mining and Metallurgical Engineers for 1919 it is gratifying to note the establishment of the Robert W. Hunt Prize for the best paper on the subject of iron and steel presented to the Institute for publication. Rules for this prize have been adopted and a medal is being designed by the distinguished artist, Mr. Emil Fuchs. Two bronze tablets have been erected at the headquarters of the Institute, one in memory of Dr. James Douglas and the other commemorative of the American Institute of Metals which was affiliated with the A. I. M. E. in the year 1918.

The Institute has also taken an advanced stand with regard to professionalism and established a precedent worthy the attention of other professional organizations in the expulsion of members believed to be unworthy the honor or privilege of membership. The report states that two members have had the privileges of membership withdrawn—as many as during the past six years—and comments as follows: "If an engineer is unworthy because of his lack of integrity, it is better that he be expelled forthwith, and members are urged for the good of the profession to bring to the attention of the Directors any cases of unprofessional conduct on the part of A. I. M. E. members. We believe that the increase in number of cases reported this year is due to the establishment by the members of a higher qualification for membership, and therefore a greater appreciation of the honor and responsibilities of membership."

### TIGHT-FITTING BOLT THREADS

(Continued from page 224)

In conclusion it may be stated that the tests would seem to indicate the following:

- 1 The cause of stripped threads is lack of room into which the metal can flow
- 2 The pitch diameter should be the same in both threads
- 3 The lead should be the same
- 4 The thread angles should differ by not more than 10 deg.
- 5 The limits for the inside diameter of nut need not be adhered to closely, as the inner part of the nut thread exerts very little, if any, holding power.
- 6 The outside diameter of plug and pitch diameter of both plug and nut are important and should be adhered to fairly closely.

### DISSIPATION OF HEAT BY SURFACES

(Continued from page 224)

of 0 deg. Then, since the watts dissipated varies directly with the temperature excess for a constant air velocity, it is seen that about 45 per cent more heat will be dissipated per degree under the above conditions of air velocity and heat supplied for an angle of incidence of about 42 deg. than for either perpendicular or parallel incidence. It is further seen that the least heat will be dissipated for 90 deg. incidence or when the coil is parallel to the air stream.

Tests were also made for perpendicular incidence of the air stream for various positions of the coil about its axis. No noticeable difference was observed other than what might well be ascribed to experimental error. This is quite significant since it shows the factor of importance to be the relative position of the axis of the coil in the air stream and not the relative position of the coil about its axis. Such a condition is quite likely to hold for all objects completely within the air stream.

## VENTURI-METER CALCULATIONS

(Continued from page 220)

$P_1 - P_2$ , that is, actual manometer readings. Interpolation could then be resorted to, and by dividing the value of  $Q/\sqrt{T}$ , found in the ordinate by the square root of the inlet temperature the flow in cubic feet of free air per minute could be obtained. The accuracy would depend upon the care taken in the interpolation. It was generally within 2 per cent, however, which was sufficient to answer the purpose for which this set of curves was devised.

## CALIBRATION

After consideration and trial of several methods of calibration, it was decided to check the meter against thin-plate orifices, using the empirical formula

$$Q = \frac{405.4 (P_1^2 - P_2^2)^{0.85}}{\sqrt{T}} \dots \dots \dots [9]$$

where  $Q$  and  $T$  are the same as before;  $A$  is the area of the orifice in sq. in.;  $P_1$  is the pressure in lb. per sq. in. abs. in front of the orifice; and  $P_2$  is the pressure in the same units beyond the orifice.

This formula, like formula [2], is due to Mr. Reynolds, and has been checked by him by means of a large number of very accurate experiments. Three orifices were used, having diameters of  $\frac{3}{8}$  in.,  $\frac{1}{4}$  in. and 0.191 in., respectively. All the plates were  $\frac{1}{16}$  in. in thickness and made of brass.

The results of this calibration are shown in Fig. 2. The coefficient seems to decrease with an increase in flow. This is not in accordance with the results obtained by several other investigators, but the orifices were later checked up and further runs made with substantially the same results. Another calibration was made after more than a year of operation of the meter, and, despite some slight corrosion and roughening of the walls, the coefficient was found to be very nearly the same. It is the writer's opinion that for most experimental work one would be very safe in assuming the coefficient of a carefully constructed venturi meter when metering compressed air to be practically unity, providing the ratio  $P_2/P_1$  was not less than 0.90.

TABLE 1 VALUES OF  $f (P_2/P_1)$  FOR VALUES OF  $P_2/P_1$  FROM 1.00 TO 0.90

$\frac{P_2}{P_1}$	$f \left( \frac{P_2}{P_1} \right)$	$\frac{P_2}{P_1}$	$f \left( \frac{P_2}{P_1} \right)$
0.90	0.1600	0.97	0.0917
0.91	0.1534	0.98	0.0753
0.92	0.1456	0.985	0.06335
0.93	0.1369	0.99	0.0535
0.94	0.1276	0.995	0.0370
0.95	0.1170	0.9975	0.02688
0.96	0.1057	1.0000	0.00000

## MANOMETERS

As stated before, it was necessary to use two manometers, one filled with water and the other with mercury. This was necessary in order to read accurately values of  $\Delta P$  from about 11 lb. per sq. in. to 0.10 lb. per sq. in. A valve and piping arrangement with which it was possible to quickly change from one manometer to the other while under pressure, and at the same time keep the liquid in the manometers from being blown out, is shown in Fig. 3. Its operation is apparent. It is necessary, however, to be sure that the valves connecting the two legs of each manometer are open when making any change of valves Nos. 1, 4 or 5, or whenever valves Nos. 4 and 5 are closed, and also that valve No. 2 remains open at all times when the water manometer is not in use.

It was found that rubber washers cut from soft sheet rubber made the most satisfactory packing for the stuffing boxes on the air, water and mercury ends of the manometers. Brass stuffing boxes and U's were used, excepting on the lower end of the mercury manometer, where wrought iron was used. Glass tube 3 mm.

outside and 1 mm. inside diameter was found to be satisfactory. At first an attempt was made to make the manometers from a single piece of glass bent into shape, but it was discovered that the internal strains set up by the heating were so great as to render the tubes unreliable when used at this pressure.

In the final set-up it was necessary to replace the  $\frac{1}{2}$ -in. piping which connected the venturi meter with the manometers with  $\frac{1}{2}$ -in. piping, and to provide small water traps or pockets at the point where these pipes were connected to the venturi meter. This was done in order to prevent water, which was frequently in the compressed air, from working its way over into the piping and even into the manometers, and thus rendering the readings inaccurate. A large number of experimental runs, otherwise perfect, were spoiled before this fact was discovered.

The total drop in pressure across this venturi tube for rates of flow under 100 cu. ft. per min. was only a fraction of a pound per square inch, while at 200 cu. ft. per min. it was only about 2.5 lb. per sq. in. when  $P_1$  was 100 lb. per sq. in. gage. At rates of flow greater than this, however, the drop increased rapidly.

## PHYSICAL BASIS OF AIR-PROPELLER DESIGN

(Continued from page 219)

mediate line undoubtedly represents different types of flow on the two parts of the aerofoil. This is possible because of the center support which divides the aerofoil into two parts. At the point of discontinuity corresponding to the second critical speed the lift reading becomes unsteady and the flow phenomena become unstable and jump from one type to another until the new form is established. Fig. 12-A shows the unstable flow of the transition, and Figs. 12-B and 8 show the flow of the final low-drift régime.

The discovery of this second critical speed is one of the novel and significant features of the experiments. Simultaneous observation of the balance and the flight vortices made the discovery possible; affording proof that the two types of flight vortices can be identified with the two values of the lift coefficient, one belonging to a high  $L/D$  régime, the other to a low  $L/D$  régime.

Various experimenters have in the past given evidence of discontinuity of the flow past aerodynamic objects. As applied to aerofoils, Mr. Orville Wright conducted in 1918 a particularly interesting series of experiments, the results of which unfortunately have not been published, wherein new discoveries were brought out regarding the discontinuity of flow about propeller sections. He found that at certain angles thick sections manifested a dual value of the coefficients, the angle at which discontinuity occurred depending on whether the angle was increasing or decreasing at the time when the readings were taken. He interpreted the phenomenon as due to a change of air flow. He found two distinct values of the lift coefficient and of the drift coefficient throughout the range of instability; the high lift value always corresponding to a low drift value and vice versa. It was possible to make the values change back and forth between the two points at will by disturbing the air current.

The writers have been able to verify conclusively Mr. Wright's assumption that his results involved a change of air flow; wherever discontinuity has been encountered in our experiments it has always been found that the drag and lift became discontinuous simultaneously, and that the high value of lift always coincided with the low value of drag.

## PRACTICAL SIGNIFICANCE OF THE RESULTS

Reference has already been made to the prospect, opened by these experiments, of developing a usable physical theory of flight. The immediate practical results have also been important, especially as regards propeller design. For example, we have demonstrated the existence of a limited tip speed.

When the critical speed at which the change in flow takes place is reached, there is in some cases a violent chattering of the

model and support; and the nature of the vibrations readily suggests a connection with the fluttering sometimes observed in propellers. The speed encountered is equal to the tip speed of slow-speed propellers, but is considerably inferior to the tip speed of the very large fast-turning propellers used on the Liberty engine.

Many static tests carried out by the writers on propellers have shown an effect which appears to be related to the discoveries made during the series of aerofoil experiments. It is well known that the ratio of propeller thrust to propeller torque must be independent of speed of revolution if both thrust and torque are proportional to the square of the revolutions. It has been found in practice, however, that the ratio of thrust to torque decreases greatly with revolution speed when high tip speeds are reached, and that it sometimes shows a rapid decrease accompanied by violent fluttering. The analogy to the results of the aerofoil tests is obvious and it is felt that considerable study is desirable in order to connect these facts in a rational manner.

We have found by practical experience that if we do not go below a value of  $V/ND$  (velocity/r.p.m. of engine  $\times$  diameter of propeller) of 0.65 we get a very fair propeller efficiency. As we have gradually increased the speed of our planes we have gone on increasing the r.p.m. of the engine and the diameter of our propellers so that the value of  $V/ND$  has remained about the same for the great majority of propellers in actual service.

We have always assumed that there was no limit to this development aside from the characteristics of the plane and engine. That is, we have made the assumption that we could double our propeller speed just as soon as we were able to double our plane speed and strengthen our engine enough to stand the stresses involved.

It now appears, however, as though there is a limit to propeller speed aside from the value of  $V/ND$  or, to use more familiar terms, aside from pitch ratio.

Unfortunately, even the speed obtainable in the McCook Field wind tunnel is not great enough to measure the limiting velocity for relatively thin sections when set at low angles, consequently we are only able to infer that it exists.

#### CONCEPTION OF LIMITING STRESS IN FLUID DYNAMICS

Mathematical studies of first importance, which are now classical, on the nature of the flow about an aerofoil have been developed by Helmholtz, Kirchhoff, Lord Rayleigh, Lanhester, Prandtl, Kutta, Karman, Greenhill, Lewis and others. Dr. Georges de Botthézat has put forward some very interesting ideas about the effect of stresses in the fluid on the nature of the air flow, and by his theory it is proper to consider in fluid dynamics the same sort of stresses with which we are familiar in solid statics.

It is Dr. de Botthézat's conception that the type of flow which establishes itself is governed by the stresses set up in the air passing the aerofoil. The unit stresses increase as the velocity rises. It is easy to conceive that a given type of flow is possible only so long as the shearing stress, developed in the fluid, does not exceed a certain magnitude which depends on the value of the viscosity coefficient. When the stress reaches a certain critical value, rupture occurs in the air-flow structure; adjacent layers of air begin to slide past each other. Since there is no longer flow similarity, the aerofoil characteristics must change in the manner described earlier in this paper.

#### BOOK NOTES

AMERICAN GAS WORKS PRACTICE. Standard Practical Methods in Gas Fitting. Distribution and Works Management. By George Wherle. Progressive Age Publishing Co., New York, 1919. Cloth, 6 x 8 in., 741 pp., illus., tables, \$4.00.

This work is intended as a general reference book on gas-works practice in this country, with special emphasis on gas-fitting practice. Approximately, one-half of the book is given to the latter topic, and the methods used in street and house distribution, standards adopted, etc., are fully described.

APPLIED MOTION STUDY. A Collection of Papers on the Efficient Method to Industrial Preparedness. By Frank B. Gilbreth and L. M. Gilbreth. The Macmillan Co., New York, 1919. Cloth, 5 x 8 in., 220 pp., plates, 1 chart, \$1.50.

This collection describes the application of motion study in various fields of activity and the methods by which it is applied. It also gives the results obtained in various cases and suggests the fields in which it may be used with benefit.

CHILTON AUTOMOBILE DIRECTORY, January 1920. Published quarterly by the Chilton Co., Philadelphia. Cloth, 6 x 10 in., 1000 pp., \$5.00.

This quarterly directory of the automobile industry contains a classified list of the American manufacturers of passenger and commercial motor-cars, automobile equipment, parts and machinery for their manufacture. The arrangement is alphabetic and the classification is quite detailed.

In addition, the book contains a directory of automobile trade associations, a table of the serial numbers of American motor cars, the standards of the Society of Automotive Engineers and various engineering tables.

ENGINEERING MACHINE TOOLS AND PROCESSES. A Text-Book for Engineers, Apprentices, and Students in Technical Institutes, Trade Schools and Continuation Classes. By Arthur G. Robson. Longmans, Green & Co., New York, 1919. Cloth, 6 x 9 in., 307 pp., illus., table, \$4.00.

This work presents a course in the systematic study of machine work and machine tools which is practical rather than theoretical in character. The methods and machines described are those used in British shops and the volume is intended for use in that country.

FATIGUE STUDY. The Elimination of Humanity's Greatest Unnecessary Waste, a First Step in Motion Study. By Frank B. Gilbreth and Lillian M. Gilbreth. The Macmillan Co., New York, 1919. Cloth, 5 x 8 in., 175 pp., plates, \$1.50.

This book is a study of fatigue in workmen and its prevention. It aims to determine what fatigue results from various types of work and how unnecessary fatigue may be eliminated and necessary fatigue reduced to a minimum. Numerous appliances and methods are described.

HIGHWAY INSPECTORS' HANDBOOK. By Prevost Hubbard. First edition. John Wiley & Sons, Inc., New York, 1919. Flexible cloth, 4 x 7 in., 372 pp., 55 illus., diagrams, tables, \$2.50.

The author has endeavored to present most of the important details of highway construction and maintenance, as briefly as possible, in such form as to be quickly available to the inspector, who wishes to be told what to do rather than what others have done under similar circumstances. Considerable explanatory matter has been included, and diagrams have been used freely to present data in convenient form for field use.

MANUFACTURE AND USES OF ALLOY STEEL. By Henry D. Hibbard. John Wiley & Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 110 pp., \$1.25. (Wiley Engineering Series.)

In this monograph the author has tried to give briefly information of present value relating to the manufacture and uses of the various commercial alloy steels, with the hope of stimulating the demand for them and extending their practical use. The steels considered are tungsten, chromium, manganese, nickel, silicon, nickel-chromium, chromium-vanadium and high-speed tool steels. Bibliographies are given for each.

THE PRINCIPLES OF ELECTRICAL ENGINEERING AND THEIR APPLICATION. Vol. 2. By Gisbert Kapp. Longmans, Green & Co., New York, 1919. Cloth, 6 x 9 in., 388 pp., 173 diag., \$6.

The present textbook is intended for all general engineering students and also as a handbook for general engineers. For the latter, the author attempts to provide a work which will give him the fundamental principles of the subject and describe their application in practical engineering, without burdening him with minute details of design. It will, the author hopes, enable the general engineer to determine whether and how any particular piece of electrical plant can be used or adapted for a particular purpose.

Volume 1, dealing with Principles, appeared in 1916. The present volume treats of the applications of these principles in electrical machines.

## Have You Ordered *Your* Copy?

The 1919 edition of **THE ENGINEERING INDEX**—a master key to the important engineering developments of the year—will soon be off the press.

It should find a preferred position on every engineer's book shelf. The engineering press of the world, comprising more than 1100 publications, representing twelve different languages, has been

systematically searched during the past year for the more than 12,000 references which have been compiled, classified, and alphabetically arranged.

### *Edition Will Be Limited*

The number of copies to be printed will be determined strictly by the number of advance orders and requests for examination, which are received.

To insure against your being disappointed, your order or request should be sent in without delay.

In case you desire to examine the volume before purchase, it will be sent subject to your approval. Sign and mail the coupon.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS  
29 West 39th St., New York City

*Gentlemen:* Please enter my order for one copy of the 1919 Engineering Index, to be mailed as soon as issued, at \$4.00 postpaid. This order is given subject to return, if I so desire, after ten days' examination.

1920

If you are a member of the A. S. M. E. place a cross here ☐ and the book will be charged to your account.

## Aeronautic Instruments

A Paper on the General Principles of Their Construction, Testing and Use, Based on the  
Work of the Aeronautic Instruments Section of the Bureau of Standards

By MAYO D. HERSEY,<sup>1</sup> WASHINGTON, D. C.

*This paper, which is a contribution from the Aeronautic Instruments Section of the National Bureau of Standards, affords a brief sketch of the general principles of such instruments. The discussion takes up successively matters relating to the construction, the testing, and the practical use of instruments for aircraft. In each case principles rather than details are emphasized. In a few instances particular instruments are described or the results of particular investigations stated, in order to illustrate the principle involved. The paper, however, does not pretend to serve as a final or comprehensive report on the subject.*

That the general field of aeronautic instruments is a less familiar one to the engineer at large than it logically ought to be, is probably due to the confidential character of the work which has gone forward during the war. Now that attention is again directed to civilian aeronautics the subject of instruments takes on great importance for two chief reasons: first, because the efficiency and safety of air navigation, especially in clouds, depend on the reliability of the instruments which are used; and second, because the whole future development of aeronautic engineering rests upon the measurement of aircraft performance, which requires suitable instruments of precision.

THE life cycle of any aeronautic instrument starts with the recognition of some distinct physical measurement that has to be made in flight; then, broadly speaking, it passes through the three main stages of construction, testing, and use; and ends by revealing the need for some particular improvement or new development, at which point the cycle begins over again.

As a convenient way of arranging the available information, we will consider in succession these different stages or processes, emphasizing only the general principles involved, but illustrating the latter by their application to particular instruments, such as the aneroid barometer or tachometer.

### 1 CONSTRUCTION OF INSTRUMENTS

In classifying instruments with regard to the purpose for which they are needed a fundamental distinction may be drawn between service instruments and experimental instruments. Service instruments have to be light and rugged, fool-proof, and reliable under all conditions of flight, and must not occupy too much space in the cockpit. Experimental instruments must be extremely accurate and the self-recording feature is desirable.

A further distinction may be drawn between instruments for balloon and airship use and those for airplanes. Historically, instruments for lighter-than-air craft were the first to be developed; but owing to the more extensive use of airplanes during the war, the scientific elaboration of airplane instruments stands now far in advance of airship instruments. The chief characteristics of airship instruments are the relatively lower range of

speed and altitude over which the mechanism has to function accurately, and the correspondingly weaker forces available to operate the movement. In addition, there are some extra instruments needed on airships, for measuring conditions relating to the air and hydrogen supply.

Finally, all aircraft instruments may be classified with respect to the nature of the measurement made. From this viewpoint the most important groups are: (1) altitude instruments; (2) speed indicators; (3) direction indicators; (4) tachometers; (5) gasoline indicators; (6) thermometers and pressure gages for the power plant; (7) timepieces; (8) oxygen apparatus; and (9) additional instruments for lighter-than-air craft.

#### ALTITUDE INSTRUMENTS

Taking up these nine groups in order, altitude instruments, broadly considered, may be regarded as covering the following species:

- a Altimeters
- b Barographs
- c Thermographs and aerographs
- d Statoscopes
- e Rate-of-climb indicators
- f Night altitude indicators.

The altimeter is in principle a common aneroid barometer with a movable altitude scale instead of a fixed pressure scale. For airplane use, however, the aneroid has to be made uncommonly well; otherwise the instrument will have serious errors caused by the peculiar conditions of flight, and the pointer may vibrate so much that it can hardly be read.

A typical altimeter is seen in the upper left-hand part of the instrument board picture, Fig. 1. The elements of its construction are probably familiar, comprising a stiff steel spring coupled to a thin corrugated-metal vacuum box, together with a delicate transmission mechanism which multiplies the movement of the box. A dilation or contraction of the box only 0.002 or 0.003 in. causes a motion of 1 in. at the tip of the pointer. Various minor adjustments are provided, and usually a bimetallic bar forms part of the lever system, serving in some measure to compensate for the influence of temperature.

Barographs usually contain a tier of vacuum boxes, one on top of another from two to five in number, with a pair of steel springs inside each box. The multiplying factor of the transmission mechanism is decidedly less than in altimeters, so that the pen arm has correspondingly greater power for tracing a firm ink line on the revolving chart.

Thermographs are intended for recording the temperature of the atmosphere at different altitudes. They have been built both with bimetallic elements and with delicate Bourdon tubes containing mercury or ether. Aerographs are combination recording instruments comprising hair hygrometers for humidity determination along with the barometric and thermometric elements.

<sup>1</sup>Abstract of a paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

<sup>1</sup>Chief, Aeronautics Instrument Section, U. S. Bureau of Standards.

Statoscopes serve to tell whether a balloon or airship is slightly ascending or descending. They are remarkably sensitive, too much so to be of much use on airplanes. The statoscope in its simplest form is a thermally insulated vessel of air, connected to the external atmosphere by a glass tube containing a drop of red liquid which moves freely one way or the other in response to any minute change of external pressure.

Rate-of-climb indicators give a direct reading of the vertical speed in feet per minute. The most usual types are based upon the pressure difference set up between the two ends of a capillary tube connecting a thermally insulated air container with the external atmosphere. What is actually observed is the manometer indication of that differential pressure.

The night altitude indicator is an optical projection instrument of the range-finder type, particularly valuable for seaplanes flying low over the water.

#### SPEED INDICATORS

The pressure type of air-speed indicator shows the impact pressure of the air due to the motion of the aircraft and so enables

type) are usually based on some rotating-vane or Robinson cup principle and connected, either directly or through electric transmission, with a tachometer movement.

Absolute or ground-speed indicators have been successfully made in the visual type which gives its result by combining an observation of the angular velocity of the line of sight with a knowledge of the altitude.

#### DIRECTION INDICATORS

The third general group, direction indicators, may be subdivided as follows:

- a* Compasses and turn indicators
- b* Inclinometers and banking indicators
- c* Angle-of-attack indicators
- d* Side-slip or yaw indicators
- e* Drift indicators
- f* Course-finding instruments.

Compasses may conceivably be either magnetic or gyroscopic, but the latter have not yet been successfully developed for airplanes. Magnetic compasses in common use are of the short-

FIG. 1. TYPICAL AIRPLANE INSTRUMENT BOARD, SHOWING ALTIMETER, TIMEPIECE, AIR-SPEED INDICATOR, COMPASS, TACHOMETER, PRESSURE GAUGES, AND RADIATOR THERMOMETER

the pilot to keep above his stalling speed and below the danger point due to excessive speed. Such instruments consist of two parts: the indicator proper on the instrument board in the cockpit (see Fig. 1), and a pressure head mounted out on some strut where it will catch the full force of the undisturbed atmosphere going by. The indicator part measures the differential pressure generated by the pressure head and transmitted to it through some length of tubing. Liquid manometers were used for the indicator early in the war, but later were superseded by various diaphragm constructions. Not only corrugated metal diaphragms, but even rubber and doped silk have been found satisfactory for this purpose.

The pitot tube and venturi tube have been tried out in a great variety of forms as pressure heads for air-speed indicators. A combination of the two gives the greatest differential pressure and was adopted in this country in preference to the pitot tube, in order to accelerate production of indicator mechanisms during the war.

Air-speed indicators of the anemometer type (or true air-speed

period type. Turn indicators have been made in both aerodynamic and gyroscopic forms. The former type measures the differential pressure between two static heads placed one at each wing tip. It is therefore a purely atmospheric instrument which might read zero if the aircraft were resting in a large portion of the atmosphere itself undergoing rotation. The gyroscopic forms show absolute rotation: one type is a very sensitive indicator showing whether the aircraft is or is not turning, and whether to the right or left, while the other type is somewhat less sensitive but actually measuring the rate of turning.

Inclinometers are to be distinguished from banking indicators in that they measure the inclination of the aircraft to the ground, while banking indicators show only the departure of the aircraft from the proper banking position. Gyroscopic inclinometers are usually of the long-period pendulum type. They function as a simple pendulum several thousand feet long, and so are free from the effects of transient accelerations, but not from persistent acceleration in the same direction. The most common inclinometers are liquid-filled tubes in the form of a large, triangular closed

circuit, and are used for fore-and-aft observations. The commonest form of banking indicator is a modification of the familiar spirit level, bent into an arc of about 20 deg. each side of the zero. Mechanical pendulum types also are in use.

Angle-of-attack indicators show the angle between the wing chord, say, and the direction of motion. Both weather-vane and differential pressure types have been used, the latter like the side-slip indicator below.

Side-slip or yaw indicators show whether the aircraft is heading exactly in the direction of motion (relative to the atmosphere) or not. It operates by the differential pressure set up between symmetrically placed openings on the two sides of a sphere, attached to some strut so as to head directly forward. The two openings are connected to the two sides of a diaphragm movement with dial and pointer.

Drift indicators show the speed of drift compared to the speed of advance and involve the rotation of some reference line by the observer until it is parallel to the apparent trajectory of objects going by on the ground.

Course-finding instruments are merely mechanical devices for determining the course and distance made good, by reference to data already available.

### TACHOMETERS

Tachometers constitute the fourth general group. All the various types serve for the sole purpose of indicating the revolutions per unit time of the propeller shaft, with the exception of one instrument which indicates also the angular acceleration of the propeller shaft, that is, its rate of speeding up or of slowing down. The diverse types of construction may be subdivided respectively as: Chronometric; centrifugal; magnetic; electric; air-viscosity and air-pump; and liquid.

The chronometric or clockwork type, the most accurate but most complicated, actually counts the number of revolutions in a fixed time.

The centrifugal type, most commonly used on aircraft, works on the principle of the change which takes place in the position of a revolving mass due to centrifugal force acting against the restoring force of a spring.

The magnetic type operates by the rotation of a permanent magnet near an electrically conducting disk which is mounted on the pointer spindle and controlled by a spring.

The electric type consists of a magnet, geared to the engine shaft, which transmits the resulting voltage to a millivoltmeter graduated to read revolutions per minute.

The air-viscosity type is similar to a torsion viscosimeter, measuring the product of viscosity by speed of rotation. Here the viscosity of the fluid, air, is so nearly a constant that the deflection of the spring and pointer is almost directly proportional to the speed of rotation. The air-pump type is based on the force of impact of the air against a movable vane resisted by a spring; the pump is geared to the engine shaft so that the deflection depends on the speed of rotation.

The liquid type involves the observation of the maximum height of a liquid column or deflection of Bourdon gage which can be maintained by a centrifugal pump geared to the engine shaft. By comparing the height of this column with that of a similar one heavily damped an indication of angular acceleration is also obtained.

### GASOLINE INDICATORS

Gasoline indicators, the fifth group, comprise, broadly speaking, depth gages and flow meters. Depth gages show the available supply and are of two types, those based on a simple float principle and those which measure the hydrostatic pressure near the bottom of the tank. Flow meters show the rate of consumption of gasoline at any instant. They have been based on the venturi principle and also on the principle of utilizing the force of impact of the stream of liquid against a movable element resisted by a spring or by gravity.

### THERMOMETERS AND PRESSURE GAGES

The sixth group comprises thermometers and pressure gages for the radiator, the lubrication system, and the gasoline tank, respectively. These thermometers are of the long-distance transmission type with liquid-filled or vapor-filled bulbs. The indicator movement, installed in the cockpit, consists essentially of a Bourdon tube element, as do also the air and oil pressure gages.

### TIMEPIECES

The seventh group, timepieces, presents no great novelty aside from the reversing stop watches used in connection with certain bomb sights; but they have to be rugged enough to withstand airplane service and provided with suitable dials.

### OXYGEN APPARATUS

Oxygen apparatus for the aviator (group 8) may be either of the compressed-oxygen, liquid, or chemical type. Only the first has been put into regular use in this country. These outfits are provided with automatic regulators which control the flow of oxygen from the storage tank to the aviator's breathing attachment. The regulators are designed to deliver an amount of oxy-

FIG. 2 AVIATOR'S OXYGEN REGULATOR

gen which increases at the higher altitudes in accordance with a prescribed formula. The mechanism is operated by diaphragms. An example of such a regulator is shown in Fig. 2.

### BALLOON AND AIRSHIP EQUIPMENT

The ninth and last group comprises balloon and airship equipment not already included among the foregoing. Special pressure gages are made for indicating the amount of water ballast carried. Delicate manometers are made for measuring the air pressure in the balloonets and the hydrogen pressure in the envelope; liquid types have been used, but sensitive diaphragms are better. Electric-resistance thermometers are used to indicate the temperature of the gas in the envelope. Hydrogen detectors based on osmotic pressure action are valuable for locating leaks.

### DESIGN, DEVELOPMENT AND PRODUCTION

The design of aeronautical instruments is at present almost wholly on a cut-and-try basis. The Bureau of Standards has made some progress, however, in placing instrument design on a rational basis. Consideration has been given to such general problems as: the stiffness of elastic systems where two bodies such as a spring and diaphragm are coupled together; the effects of temperature and elastic lag on coupled systems; bimetallic bars for temperature compensation; the balance of

moving parts to resist angular acceleration and vibration; the securing of a uniform scale by suitable design of transmission mechanism; and the treatment of aerodynamic problems and the general action of damping fluids by the method of dimensions described before this Society by Dr. Buckingham at the Buffalo meeting in 1915 in his paper on Model Experiments. There is hardly space here even to outline those results, which it is hoped may form the substance of later communications.

Experimental development has to follow the preliminary design of an instrument before it can be put into quantity production. Among the recent development projects of the Aeronautic Instruments Section at the Bureau of Standards may be mentioned the following, several of which were undertaken at the request of the Air Service or the National Advisory Committee for Aeronautics:

- a* The conversion of barographs from a low-altitude to a high-altitude range, together with the elimination of ink.
- b* The conversion of altimeters from an altitude scale to a pressure scale, to adapt them for aircraft performance testing. Improvements were also made in the method of mounting the main spring of commercial altimeters to diminish the ob-

*g* A working model of a type of dynamical ground-speed indicator which would become available if there existed a suitable gyro-stabilizer to hold it horizontal. This model consists of a large steel ball free to roll back and forth in a glass tube filled with a viscous liquid. It can be shown mathematically that if the fluid resistance is directly proportional to the speed of the ball through the tube, while the tube is held in a horizontal fore-and-aft position, then the displacement of the ball at any instant from its initial position in the tube is directly proportional to the absolute ground speed of the aircraft.

The development work on any given model of an instrument must be dropped and the design rigidly fixed before quantity production can be efficiently carried on. In this country the quality of products made in quantity has to be artificially held up to standard by means of specifications and inspection. This situation is not so commonly met with abroad, especially in France, where every individual involved, from the mechanic in the shop up to the head of the concern, takes a professional artistic pride in the quality of his output. This difference is not the fault of

FIG. 3. TESTING OUTFIT FOR AIRPLANE TACHOMETERS

served differences between readings with increasing and decreasing altitudes.

- c* The development of a precision altimeter with a large dial giving a  $\frac{1}{4}$ -in. movement of the pointer for each 100 ft. of altitude, a special design being made for the elastic system to diminish elastic lag.
- d* The development of a direct-reading rate-of-climb indicator based on the capillary-tube-leak principle, with the use of a liquid entirely dispensed with through the use of sensitive diaphragms.
- e* Development of a reduced scale working model of a proposed gyro-stabilizer on the long-period pendulum principle, possessing mechanical features of extreme simplicity.
- f* The application of the moving-picture camera for securing a record of instrument readings during the performance test of an aircraft in flight. The whole outfit—instruments, illumination, camera and timing system—forms a unit which takes the place of the human observer in the airplane.

the American manufacturer, and there are some advantages in our system, yet the fact remains; and this spectacle of successful instrument production without specifications formed one of the most astonishing impressions which the writer gathered from his trip to Europe during the war.

## 2 TESTING OF INSTRUMENTS

The testing of any aeronautic instrument consists in a direct comparison with some standard, the instrument being operated over its full scale; the whole procedure should then be repeated under different conditions varying in flight. The most important of these conditions are:

- a* Extreme low temperatures
- b* Change in pressure or density of air
- c* Acceleration and inclination
- d* Vibration
- e* Time elapsed during the flight.

A typical installation of testing apparatus, in this instance for the testing of tachometers, is shown in Fig. 3. The results of such a test are ordinarily given out in the form of tables or curves showing the correction of the instrument from point to point of its scale. By the correction is meant the amount that has to be added algebraically to the reading of the instrument in order to give the true value of the quantity measured. Typical correction plots or curves of this sort are seen in the first two charts shown on Fig. 4.

Factory inspection tests can be reduced to a comparatively simple routine after the first few instruments of each pattern have been inspected. The purpose of such tests is to control the quality of the output.

The short test for service instruments is an attempt to secure, in a minimum time, such data regarding the maximum calibration correction or temperature effect as may be needed for actual refer-

ence on the nature of the work for which the instrument is to be used, and on the flight conditions which will prevail. For instruments such as aneroid barometers, which involve serious errors due to elastic lag or temperature lag, there can be no more reliable method of determining the corrections necessary for the interpretation of the readings than to make a flight-history test by actually reproducing in the laboratory the identical variation of pressure, temperature, etc., which was experienced from time to time during the flight. This is particularly important in connection with the use of barographs for competitive altitude flights. It is now well known that barographs subject to any appreciable amount of elastic lag will read a higher altitude the greater the time elapsed during the flight.

It is a short step from some of these more complete testing methods to the general subject of the experimental investigation of sources of error in instruments. Such investigations have

a-Calibration with Direct Return

b-Calibration with Delayed Return

c-Change in Reading with Time, at Constant Pressure

d-Calibration of Same Aneroid at Three Temperatures.

e-Calibration for Temperature at Constant Pressure.

FIG. 4. TYPICAL INVESTIGATION RESULTS

ence in connection with the installation or use of instruments on aircraft.

The Bureau of Standards general test is the one which is furnished on instruments submitted to the Bureau without special instructions. It is a comprehensive standard form of test affording a complete calibration curve together with, at least, numerical values for the more common errors due to temperature and other well-known conditions.

The Bureau makes more thorough tests on sample instruments of new type whose mechanism is not familiar. Such additional observations usually include some form of accelerated life test, such as a five-day run to determine the endurance of the instrument under vibration. The steadiness of the pointer and the accuracy of the instrument with and without vibration are observed in such a test.

The special tests on experimental instruments depend of

formed one of the most interesting features of the work of the Bureau of Standards and are illustrated by the examples given in Fig. 4.

In this figure five charts are shown based on experiments with high-grade commercial aneroids. The first chart (a) shows the ordinary calibration of an aneroid changing the pressure at the rate of an inch of mercury in five minutes. (At sea level one inch of mercury corresponds to about one thousand feet of altitude. At twenty thousand feet one inch corresponds to about two thousand feet of altitude). The calibration curve would be distinctly different at some different speed, due to elastic lag in the corrugated-metal vacuum boxes. For the same reason, as shown in chart b, the discrepancy between the readings going up and coming down is much greater when the aneroid is held at the maximum altitude for a considerable time interval. This drift, or change of reading at constant pressure, is shown in chart c as a

function of the time elapsed. These curves may be taken as a criterion of the elastic quality of the material in the instrument; and several hundred such have been determined in the course of the Bureau's investigations. Chart *d* shows the increase in the width of the hysteresis loops with rise of temperature, and it also shows the decrease in the sensitivity of the movement when an instrument is chilled. This last effect is largely due to the change of elasticity with temperature, and cannot be fully compensated for by means of the ordinary bimetallic lever. The remaining chart (*e*) shows what can be done in the way of temperature compensation. Of three superimposed curves one represents a typical uncompensated aneroid. The graphs show the change of reading with temperature at a constant pressure corresponding to sea-level conditions. A second curve shows a partial degree of compensation obtained by admitting air to the vacuum box. The remaining curve shows satisfactory compensation by means of a bimetallic bar for sea-level observations; but this same aneroid may have a serious temperature error when the movement has shifted into the new position which it will occupy at twenty thousand feet.

Still further characteristics of aneroid barometers have been studied at the Bureau in addition to those shown in Fig. 4, and similar investigations have been extended to all of the other aeronautic instruments.

### 3 USE OF INSTRUMENTS

Many practical airplane pilots disclaim the use of instruments, and certainly it is desirable that the aviator should be trained to become just as independent of any mechanical aid as possible.

Some of the times when airplane instruments are really of the most importance are the following:

- a* For various military and naval operations such as bomb dropping
- b* Long-distance navigation
- c* Flying at night and in clouds
- d* Preparing to land on a perfectly smooth body of water where the height is deceptive
- e* Flying in formation with instructions to hold to a prescribed air speed and altitude
- f* Photographic and survey work.

The need for instruments is still more evident in airship work. Here it is necessary to control the position of the ship, especially near the ground, with comparatively greater precision; nor is it possible for the pilot to act so quickly in response to his unaided senses as it might be in an airplane.

The following precautions may be suggested for getting the best results in the practical use of service instruments:

- a* Select for installation in the first place only those instruments

which can be certified by the Bureau of Standards as suitable for the intended use.

- b* In any event see that the instrument is tested immediately prior to installation to avoid the occurrence of large errors due to secular changes or mechanical injury.
- c* When accuracy is required in flight observations the aviator must remember where appreciable lag errors are stated to exist, whether due to elastic lag or temperature lag or other causes, that some time will be required for the instrument to completely respond to any given change, and that the results will be different with increasing and decreasing scale readings.
- d* At least once in six months it is desirable that instruments should be overhauled, during which time they may perhaps be replaced by a reserve supply of fresh instruments properly tested and adjusted.

The problem of salvaging has been studied by the Bureau of Standards and the statistical results of such work are of the greatest value as a basis for future improvements in instrument construction. The actual salvage proposition consists of dismantling a certain number of damaged instruments and putting them together again so as to form a smaller number of good instruments. The study of expedients for readjusting the mechanism forms an integral part of such work. This can only be done in the testing laboratory.

In concluding this paper, a recapitulation may well be made of some of the outstanding problems of instrument development, the solution of which is much to be desired:

- a* A satisfactory gasoline depth gage is needed.
- b* Barographs and other recording instruments of better quality than any now existing are needed. Better clockwork, and a much more open scale, and more complete freedom from errors due to friction, temperature, elastic lag, and lack of balance are desirable.
- c* A wholly satisfactory form of compass for airplanes is not as yet available. Besides the northerly turning error, so-called, to which all single-pivot compasses are necessarily subject, there are troubles due to the action of the damping fluid.
- d* Air-speed indicators suitable for the low speeds of airship flight are required.
- e* A gyro-stabilizer is needed, different from existing types in that it must be able to stabilize a body which is not rigid, but contains a freely moving mass. Such a stabilizer is necessary before the full possibilities of any dynamical type of ground-speed indicator can be realized.

The material in this paper is of course not due to any one individual, but is based upon the work of the entire Aeronautic Instruments Section of the Bureau of Standards. Later, the detailed official reports prepared by the various members of the staff concerned, should be available through the publications of the Bureau and the National Advisory Committee for Aeronautics.

## The Rectilinear Flight of Aeroplanes

Basic Principles of Analytical Theory Advanced by Eminent French Engineer and Scientist and Their Application—Calculation of Maximum Cruising Radius

By A. RATEAU,<sup>1</sup> PARIS, FRANCE

**I**N his paper, of which the following is an abstract, M. Rateau presents the basic principles underlying his theory of the rectilinear flight of aeroplanes, and further indicates how they may be applied in the solution of certain important aeronautical problems. In doing this he establishes at the outset characteristic relations connecting the main factors governing the operation of the propeller.

The paper is based on the assumption that a constant-compression, not supercharged, engine is used, the carburetor being

equipped with an altitude regulator, in order to maintain the mixture at the optimum ratio all the time, and that further the propeller is of constant pitch, is not subject to deformation, and is held on the motor shaft.

The same theory may apply to a propeller with gear reduction, but the author does not wish to introduce into his equations the complications created by the use of gear reduction between the motor and propeller.

One of the most essential elements affecting flight is the specific weight of air at the different altitudes, and the author establishes a formula connecting the specific weights of air at the ground and at various elevations.

As regards the engine, the most important factor is not the

<sup>1</sup> Mem. Institut de France; Hon. Mem. Am. Soc. M. E.

Abstract of paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Advance copies of the complete paper may be obtained gratis on application. All papers are subject to revision.

power output, which varies with the speed, but the couple which it sets up, and if the carburetor is properly adjusted this couple should vary but little with the speed of rotation in revolutions. It is, however, tremendously affected by the specific weight of the air sucked in, though not proportional to it.

On the other hand, the consumption of fuel and oil in an engine varies with the speed of rotation and with the specific weight of air. As regards fuel consumption, if the carburetor is properly adjusted it varies in proportion to the total weight of the air sucked in, and hence in proportion to the speed of the engine and to the specific weight of air. The oil consumption depends on the character of the oil and the temperature of the air with which the engine is supplied, and increases with the speed of the engine more rapidly than the speed itself.

The consumption of both fuel and of oil is affected by a number of factors in such a manner that it is impossible to keep track of them in an exact manner. It may be said to be proportional to  $\omega + \sigma$  where  $\omega$  is the specific weight of air and  $\sigma$  is a constant, the numerical value of which is about 0.08 in the case of non-rotary motors lubricated by castor oil and a little larger, say, about 0.1, in the case of mineral oil, and still larger for rotary engines.

Considerable attention is devoted to the characteristic functions of the propeller. In this connection only the effective pitch of the propeller and not the so-called "nominal pitch" is taken into consideration. While the effective pitch is of a physical character and therefore cannot be measured directly on the propeller, it is nevertheless of the nature of a constant characteristic of the propeller, no matter what the speed of the latter may be.

The following basic formulæ are established by the writer:

Theory shows that the tractive force  $F$  of the propeller in kilograms and its countering couple  $\Gamma$  in kilogram-meters are expressed by the relations

$$\left. \begin{aligned} F &= b\omega n^2 f(\sigma) \\ \Gamma &= \frac{bH}{2\pi} \omega n^2 \varphi(\sigma) \end{aligned} \right\} \dots\dots\dots [1]$$

where  $f(\sigma)$  and  $\varphi(\sigma)$  are the functions of slip and of certain coefficients of the propeller mentioned later, and where  $b$ , which the author calls the factor of thrust, has for its expression in the case of aeroplane propellers with narrow blades—

$$b = \frac{2k\pi}{g} HM \dots\dots\dots [2]$$

where  $\pi$  is the ratio of circumference to diameter;  $g$  the gravitational constant in metric units ( $= 9.81$ );  $k$  a numerical coefficient of the order of 2, and  $M$  the moment, referred to center of propeller, of the projection of the active surface of the wings on a plane perpendicular to the axis. The units in the case of  $H$  and  $M$  are the meter and the square meter.

The function  $f(\sigma)$  is of the form  $\sigma(1 - c'\sigma)$  where  $c'$  is the coefficient depending on the ratio  $p$  of the pitch  $H$  to the peripheral diameter  $D$  of the propeller and decreases in a certain proportion to the decrease of the ratio above referred to. When  $p$  is less than unity (and this is the case with practically all aircraft propellers),  $c'$  is less than 0.01. Since, on the other hand, the slips  $\sigma$  as a rule vary only from 0.2 to 0.4, it can be seen why the corrective term  $c'\sigma$  varies only by about 0.016 in particular applications and hence may be entirely neglected when subtracted from unity. This is what the author does. At the same time, whenever necessary, the complete formula makes it possible to carry out the calculations with the necessary degree of precision.

The function  $\varphi(\sigma)$ , which is of basic importance, has the form

$$\varphi(\sigma) = a + \sigma - e\sigma^2 \dots\dots\dots [3]$$

where  $e$  always has a value in the neighborhood of 0.5 and  $a$  of 0.03, and are variable from one propeller to another in accordance with its shape and roughness of the surface. It is only this  $a$  that is affected by losses in the propeller due to shocks, friction and turbulence of the fluid; it is connected with the coefficient  $\epsilon$  (loss of relative velocities across the propeller) by the formula—

$$a = \epsilon \left( \frac{p}{\pi v} + \frac{\pi v}{p} \right) \dots\dots\dots [4]$$

where  $v$  is the ratio of a certain average radius to the radius of the periphery.

If it be assumed that  $e = 0.5$ , then

$$\varphi(\sigma) = a + \sigma - \frac{\sigma^2}{2} \dots\dots\dots [5]$$

and hence

$$\psi = \frac{\varphi(\sigma)}{f(\sigma)} = 1 - \frac{\sigma}{2} + \frac{a}{\sigma} \dots\dots\dots [6]$$

This function  $\psi$  of the slip is one that constantly occurs in the author's aeroplane formulæ.

The efficiency of the propeller  $\epsilon$ , if by  $v$  is denoted the velocity of advance, is

$$\epsilon = \frac{Fv}{2\pi n \Gamma} \dots\dots\dots [7]$$

If  $v$  is replaced by  $nH(1 - \sigma)$ , and  $F$  and  $\Gamma$  by their expressions taken from Equation [1], then

$$\epsilon = \frac{f(\sigma)(1 - \sigma)}{\varphi(\sigma)} = \frac{1 - \sigma}{\psi} \dots\dots\dots [8]$$

Attention is called to the fact that in this expression of the efficiency of the propeller, in which  $\psi$  may be used in the form given by Equation [6], only the slip  $\sigma$  and the coefficient of losses  $a$  are used.

FIG. 1. VARIATION OF FUEL AND OIL CONSUMPTION PER KILOMETER OF FLIGHT WITH VARIATION IN DISTANCE OF PLANE FROM ITS CEILING DURING FLIGHT. (COMPUTED FOR AEROPLANE-TYPE)

All these novel and fundamental formulæ are excellently confirmed by experiments as precise as one could wish for in a subject of such complexity as the one under consideration.

#### CHARACTERISTIC FUNCTIONS AND COEFFICIENTS OF AN AEROPLANE

For a given aeroplane the essential variables are its weight  $P$  in kilograms and its incidence  $\alpha$ , that is, the angle in degrees formed by the wings with the trajectory.

Formulæ are established connecting in horizontal rectilinear flight the weight of the aeroplane  $P$  and the resistance  $R$  to forward motion, where both  $P$  and  $R$  are expressed in terms of specific weight of air  $\omega$  and velocity of movement of the plane  $v$  in the form of

$$P = Y\omega v^2 \dots\dots\dots [9]$$

and

$$R = X\omega v^2 \dots\dots\dots [10]$$

where the coefficients  $Y$  and  $X$  for each given plane are functions of the incidence  $\alpha$ . As such they are expressed in the form of

$$\left. \begin{aligned} Y &= Y_0(1 + \eta\alpha) \\ X &= X_0(1 + \xi\alpha^2) \end{aligned} \right\} \dots\dots\dots [11]$$

where  $Y_0$ ,  $X_0$ ,  $\eta$  and  $\xi$  are the four specific coefficients of an aeroplane which have to be determined by measurement or computation.

As an example, the author considers a supposititious airplane

# River Transportation in the Mississippi Valley

## Recent Progress in Construction and Operation of Barges and Towboats—Need for Waterways Transportation—Developments Under the Federal Control Act

By E. W. SCHADEK, ST. LOUIS, MO.

*A review of recent progress in the construction of barges and towboats for river transportation, particularly in the Mississippi River Section, and of provision made for their operation. The towboats are of the screw-tunnel type with new features. Traffic by rail in the Mississippi Valley has long since reached the capacity of the railroads. The need for water transportation facilities was recognized by the Government during the war, and under the Federal Control Act appropriations were made for the construction and operation of river fleets. When the vessels are completed and placed in service, a good start will have been made in utilizing our national waterways for the development of industries and commerce.*

**T**HAT great part of our country lying between the Allegheny and Rocky Mountains, known as the "Mississippi Basin," contains more than one-half of the country's population and produces three-fourths of its food products and one-half of its manufactured products. The Mississippi Valley district includes 21 states and has an approximate area of 1,725,000 square miles, with 120 cities having a population of more than 25,000 each. It furthermore contains a number of great ports and in addition the country's greatest waterway.

The capacity of the railroads of the Mississippi Valley has long since been reached. Every one knows of the annual shortage of cars during the crop-moving season, but few realize how greatly this interferes with the flow of commodities from farmer to consumer. To provide ample rolling stock, trackage and terminals to take care of this peak load, however, would impose on the railroads too great an investment in equipment for a comparatively short period of the year, so that the only remedy for the situation is the improvement of waterways as recommended many times by the engineers studying this situation. It has been computed that the capital saving in rolling stock of the extra equipment alone would pay for the entire cost of the waterway improvement within a comparatively few years.

Our government has spent many millions of dollars upon the river improvements in the last 40 years, but hardly one-half of the necessary work has been accomplished up to the present time.

The Newton Bill, pending in Congress, calls for completion of the improvements, and covers:

- 9-ft. channel in Ohio River from Pittsburgh to Cairo
- 9-ft. channel in Mississippi from Cairo to New Orleans

- 8-ft. channel in Mississippi from Cairo to St. Louis
- 6-ft. channel in Mississippi from St. Louis to St. Paul
- 6-ft. channel in Missouri River from Kansas City to Mississippi River

### PROVISION MADE DURING THE WAR FOR NEW FLEETS AND THEIR OPERATION

During the World War the Government recognized the importance of adequate waterways in time of need. The Federal Control Act appropriated funds for new fleets and for immediate operation upon inland waterways in which were comprised the following developments:

An appropriation for the Mississippi-Warrior section provided for the construction of a new fleet on the lower Mississippi River, to consist of six tunnel towboats, 200 ft. by 40 ft. by 10 ft. in dimensions, and 40 new steel barges each 230 ft. by 45 ft. by 11 ft. The larger number of these barges is completed and the balance, according to reports, will be ready before June 1. Deliveries of the six new steel towboats were scheduled for March, June, and July, so that the complete fleet is expected to be in operation by the end of July.

The barges under construction for the lower Mississippi River have a capacity 2000 tons each, on 8 ft. draft, which is twice the capacity of the largest barges operated in the present fleet. One barge has a capacity equal to 100 cars. The towboats for this new fleet are of 1800 hp. each, with a capacity to tow downstream five of these barges, making a total of 10,000 tons, or 500 ear-

loads. An appropriation of about \$5,000,000 provides for the construction of a new fleet on the Warrior, Alabama and Tombigbee Rivers, to consist of four steel, self-propelled barges of the double-tunnel type and three tunnel towboats, each 140 ft. by 24 ft. by 6 ft. As the bulk of the tonnage on these rivers consists of coal from Alabama fields to New Orleans and Mobile, 20 steel cargo retainers of 10 tons capacity each were constructed to stimulate other cargo for northbound trips, and derricks are being installed at terminals to facilitate handling.

In the very near future there will not be a city or town on the Warrior and Tombigbee River without port facilities. Plans are being drawn and estimates made of the cost of terminal facilities at Demopolis and Jackson, and also at Spocari, six miles from Demopolis. Two turning basins are to be established on the Warrior River, one directly opposite the port of Birmingham and the other at Locust Fork. These basins, dredging work for which

will start shortly, will enable the boats to turn without backing. Craft with high stacks which cannot pass under Ensley Bridge will use the Birmingham basin.

The New York Barge Canal is to receive 20 modern power self-propelled barges each 149 ft. by 20 ft. by 12 ft. and 51 canal barges each 150 ft. by 20 ft. by 12 ft. Some concrete barges are also being built, but these are too heavy for shallow draft.

The Inland Waterways shipbuilding program above outlined would not be complete without reference to the \$3,860,000 appropriation of the Emergency Fleet Corporation for the Upper Mississippi River fleet, which will consist of 19 of the most up-to-date barges, each 300 ft. by 49 ft. by 10 ft., and four stern-wheel towboats 230 ft. by 58 ft. by 8 ft. This fleet is being built under the direction of the U. S. War Department, Engineers Office, St. Louis District, headed by Major Wilbur Willing, and Mr. Wm. S. Mitchell, Assistant Engineer, who are directing the designing and construction.

#### PARTICIPATION IN BOATBUILDING BY ST. LOUIS

When the Government program of building river fleets became known to some of the leading citizens of St. Louis they decided that this city should also be represented in the shipbuilding program. A shipbuilding company was accordingly organized and incorporated under the name of St. Louis Boat and Engineering Company, of which Mr. Edward A. Faust and Mr. Albert Ruehmeli are the leaders.

On account of the war and later the post-war conditions, the necessary equipment and arrangement of the shipyard was delayed to such an extent that the company could not start operation early enough to secure any of the orders for the construction of the Lower Mississippi River fleet; but when the proposition for building the Upper Mississippi River fleet came up, the company was ready and received an order for two of the powerful stern-wheel towboats.

The U. S. Railroad Administration awarded the contract for the construction of four self-propelled barges for the Tombigbee, Alabama and Warrior Rivers to the St. Louis Boat and Engineering Company, and these boats are now being built in the first St. Louis construction shipyard. They are of the twin-screw steel tunnel type, 280 ft. long, 49 ft. wide and 10 ft. deep, and are built for a maximum draft of 7 ft. They are of single-deck, shallow-draft, flat-bottom type, built entirely of steel. The machinery enclosure is located aft, and the cargo space is all on deck, consisting of two steel houses for package freight, one forward and one aft, and two steel guards amidship forming coal-cargo space. The forecastle head is raised to accommodate part of the crew, and other crew quarters are located above the machinery enclosure. The pilot house is raised and the captain's room is located above. The center-line bulkhead extends from keel to deck and from forward collision bulkhead to engine-room bulkhead, all watertight. The cross bulkheads in these barges are six in number.

The propelling machinery consists of two 400-hp. vertical, triple-expansion condensing engines, and of two marine-type water-tube boilers for 250 lb. working pressure, arranged for forced draft, for which a fan of 10,000 cu. ft. of air is provided. All auxiliaries are arranged for running condensing to collect the condensate for feedwater, and the make-up water is carried along in tanks, two of which are forward underneath the crew quarters and the other four are next the engine room. The total capacity of these six tanks is 135 tons of water. The surface condenser has  $3\frac{1}{2}$ -in. outside diameter tubes with 1100 sq. ft. of condensing surface. The propellers are four-bladed, two in number, each 6 ft. 4 in. in diameter, 6 ft. 9 in. pitch.

The most interesting feature of the construction of these self-propelled barges is the selection of propeller drive instead of the paddle-wheel drive which, up to the present time, has been in use on our rivers. It is known that the propeller drive is 25 per cent more efficient than paddle-wheel drive, permitting more compact arrangement of machinery and reducing not only the size and initial cost of the boat, but also its operating expense.

#### SCREW-TUNNEL VS. STERN-WHEEL TOWBOATS

The origin of the screw-tunnel type of boat is found in the English patent of Yarrow and Company for a hinged flap forming the adjustable tunnel for a screw propeller. In this country the few attempts which have been made to replace the stern-wheel towboats with screw-tunnel boats have met with little success because the latter type of boat has not been found effective for towing purposes. While making curves with tow, towboats must flank or reverse the rotation of the wheel or propeller, in order to throw water against the rudders so as to turn the tow, which precedes the boat, and prevent its grounding on the bank of the river. The rudders of a stern-wheel towboat are connected in parallel and at flanking the boat will throw against the rudders all the water the wheel is capable of handling, making a powerful flanking.

The present tunnel towboats, besides having the ability to steer and flank, are also able to twist (where one engine runs forward and one astern). Their flanking ability with both engines running astern, however, is less than one-half that of stern-wheel towboats, and twisting, combined with flanking, reduces the total ability to handle the tow to about one-third that of stern-wheel boats. All this is well known to river "rats," hence their skepticism about tunnel towboats.

The new-type tunnel boats now being built will overcome the defects of the present-type tunnel boats by introducing independent control of starboard and port-side rudders. A tunnel towboat has one rudder forward of each propeller and one aft of each propeller, and these rudders up to the present time have been connected in parallel. The new tunnel boats will have rudders, one forward and the other aft of propeller on port side, controlled by one steering mechanism; and in the same way rudders on the starboard side will be controlled by another steering mechanism. All is ingeniously constructed so that the rudders can be operated in parallel or independently, either by power or by hand, from pilot house or forecastle.

By independent control of the two sets of rudders, the total ability to handle a tow combines that which comes from steering, twisting, flanking and side thrust of propellers, so that, when steering is not sufficient for handling the tow, the ability of flanking is increased by the ability to twist and side thrust, making the total ability to handle the tow as great as for the stern-wheel towboat, when this ability is based on the proportions of available horsepower propelling the boats.

The ingenious design of this rudder control was introduced and designed by the well-known firm of naval architects, Cox and Stevens, of New York. They have been engaged by the U. S. Railroad Administration to design and direct the construction of the new fleets as previously outlined.

#### IMPORTANCE OF WATERWAYS TRANSPORTATION

When all the vessels comprising the U. S. Railroad Administration program are placed in service, a fairly good start will have been made in utilizing our national waterways for the development of the industries and commerce of the Mississippi Valley. The importance of the waterway transportation to the development and welfare of any state or city is clearly shown in the project for which the state of Illinois appropriated \$20,000,000. The project is to connect the terminus of Chicago drainage canal in the Desplaines River at Lockport with the Illinois River at Utica, a distance of about 60 miles. When this is completed the route from Chicago to the Gulf will be realized. Time for construction of the new canal is estimated as 5 years and the carrying capacity of this new waterway 60,000,000 tons a year. The capacity of the Government's new fleet for the Lower Mississippi River between St. Louis and New Orleans is 1,000,000 tons. This gives us an idea what is still to be accomplished in building new fleets to fully utilize the waterways transportation.

There are now 600 firms in St. Louis selling in foreign markets and they did about \$75,000,000 worth of foreign trade business in 1918, increasing this about 25 per cent during the year 1919.

# The Separation of Dissolved Gases from Water

Description of a Method Therefor, Together with Particulars Regarding Its Use in Inhibiting Corrosion in Boilers and Economizers and in Increasing the Conductivity of Surface Condensers

By J. R. McDERMOT, PITTSBURGH, PA.

*This paper covers the results of a research on the separation of dissolved gases from water, both on a laboratory and a commercial-plant scale. Fundamentally the process consists of the rapid injection of heated water into a region of vacuo, and an explosive boiling of it at the expense of the heat of the liquid available to the vacuum, with a simultaneous recovery of the heat liberated to the vacuum by a heat exchanger or condenser cooled by the incoming water, preliminary to its heating. It is possible to deduce from a résumé of existing knowledge the results to be expected in the elimination of corrosion from boilers and economizers fed with oxygen-free water. Test data are submitted to show the economies to be gained from the surface condensation of steam free from non-condensable gases both in increased conductivities and higher vacua, and chemical analyses suggest the elimination of carbonates dissolved in water as bicarbonates in excess of their true solubility as carbonates.*

THE idea upon which the method of separating dissolved gases from water described in the present paper is based was originated by Mr. W. S. Elliott of Pittsburgh and sponsored by him for development under the industrial fellowship system of the Mellon Institute of Industrial Research, Pittsburgh, Pa. It appeared at the conclusion of the laboratory investigation that the process evolved from the idea successfully fulfilled three requirements which were regarded as necessary for commercial utility: It was able to handle water in quantities sufficient for the feeding of power-plant boilers with a minimal operating expense and was particularly applicable to this service; it was capable of removing all of the dissolved gases in a commercial sense; and it involved no methods or apparatus with which the average operating engineer was not familiar. The scale of experimentation was therefore enlarged, but the basic idea underwent no change.

The solution of gases in water obeys Henry's law, which states that a solvent in contact with a gaseous mixture dissolves the component gases in proportion to the partial pressures which they exert, provided they do not unite chemically with the solvent. Carbon dioxide which unites chemically with water deviates from this law, but is itself of variable content in atmospheric air. With this reservation in mind, it is possible to say that if extraction is complete, the gas mixture extracted from water is precisely of the same composition as air from which solution was attained. At incomplete extractions proportionality factors between the components appear due to different degrees of solubility. The process with which this paper deals might therefore with perfect propriety be called "air separation."

The initial laboratory installation consisted of an instantaneous water heater drawing its water under pressure from a supply main, and delivering heated water under thermostatic control to the spray head of a separator. The separator consisted of an airtight steel tank with a series of copper return-cascade pans supported by a central steel column, over which the spray head delivered water uniformly in a thin sheet. The separator tank was connected with a barometric tail-pipe column at the bottom to remove the treated water and with an air-pump connection at the top. Vapors and gases were withdrawn from the air-pump connection through a small condenser cooled by the supply water to the heater, and equipped with a trap for retaining condensate. Non-condensable gases were withdrawn from the condenser by a variable-speed motor-driven air pump and passed to a displace-

ment air bell, adapted from a standard gas-meter prover, for collection and measurement. Thermometer wells were installed to indicate all significant temperatures and weighing tanks to collect and measure treated water. The condensate trap was so valved that it could be cut in and out of the system for the purpose of collecting the condensate over stated periods, and the air bell collected all non-condensable gases. While the provisions for determining all data but volume of non-condensable gases proved adequate and satisfactory, it was immediately discovered that the air-bell data were not of consistent accuracy in spite of the laboratory tightness of the complete system. It was accordingly necessary to turn to direct testing of the water which had passed through the process. The laboratory arrangement is indicated in the diagram of Fig. 1.

Three methods, developed previously by experimenters in other fields, were utilized in testing for the dissolved gas content, after careful checking had established their accuracy; (a) The iodometric titration method of Winkler for dissolved oxygen; (b) Freeman and Preusse's modification of Reichardt's method of boiling; and (c) a displacement with either carbon dioxide or hydrogen. As experience soon demonstrated, the degree of separation of dissolved gases was so complete that the proportions of constituent gases were the same as for atmospheric air. When this fact was definitely confirmed by a long series of pipette analyses, reliance was placed entirely upon the chemical titration method of Winkler.

At the conclusion of about four months' intermittent testing the apparatus was taken apart and examined. Steel tank, copper pans and condenser gave evidence of very accelerated corrosion. Cognizance of this virulent action was taken in the design of the first commercial apparatus, and the separator was made entirely of cast iron and non-corroding bronzes, which materials have withstood the corrosive tendencies for over four years of experimental operation.

The laboratory experiments also developed a further fact which was the cause of much confusion at the outset. Water which has been passed through this process and completely degasified is never in equilibrium with the temperature as far as solubility is concerned. Such water has an enormous avidity for redissolving small amounts of air and it is only by the most painstaking manipulation that accurate results are possible in the determination of the extent of separation. In the practical application of the process, absolutely rigid exclusion of air must be maintained if the full benefits of the process are to be secured.

Empirical design factors governing separator volumes, pan areas, and the proportioning of the injection nozzle were adopted from the laboratory installation and embodied in the first commercial installation which was put in service in the Jeannette, Pa., works of the Elliott Company of Pittsburgh in the autumn of 1915. This installation has been in routine operation since that time. The separator proper was designed for 1000 boiler hp. at the outset, and consisted of a 100-hp. Elliott cylindrical heater shell with modified water injection, different proportions of water-storage volume and pan area, and a change of materials to resist corrosion. This design of separator has been retained intact, but the auxiliary arrangement has been modified three times. At the outset a 300-hp. open feedwater heater was installed to supply hot water, and vacuum was maintained by a rotary motor-driven dry-air pump in series with a condenser. Condensate from the condenser was allowed to drain back into the separator, and the air pump discharged non-condensable gases directly into the atmosphere; otherwise the scheme of connections was identical with that in Fig. 1.

<sup>1</sup> Research Engineer, the Elliott Company. Assoc. Mem. Am. Soc. M.E. Abstract of paper to be presented at the Spring Meeting, St. Louis, May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Advance copies of the complete paper may be obtained gratis on application. All papers are subject to revision.

An increase in boiler capacity later made necessary the installation of a 1000-hp. heater of the same shell type as the separator, and the entire outfit was repiped and made into an integral vertical unit as shown in Fig. 2. Simultaneously the mechanical air pump was replaced by a steam ejector and the condenser was mounted on the atmospheric side to recover the ejector steam, condensate drainage being now into the heater instead of the separator.

It was felt at the beginning that condenser conductivities would be very low on such vapor mixtures as are withdrawn from the separator of an air-extraction apparatus, and a condenser of a relatively large capacity was installed. This condenser was removed from the apparatus when opportunity permitted and tested under the same circulation rates and with steam-air mixtures of

in thin sheets exposed to a vapor mixture corresponding in pressure to the vacuum maintained. Under steady conditions of operation at a pressure reduction in the separator of 10 in. of mercury and admission temperature of 212 deg. Fahr., this vapor mixture corresponds to an air content roughly 0.11 per cent by weight but 0.07 per cent by volume. The water vapor is undoubtedly in equilibrium with its liquid, and as such is relatively dense and moist. With a separator water-storage volume corresponding to two minutes' operation at rating, it is impossible to detect at any rate of operation a temperature depression in the vapor mixture or in the water leaving the separator below that corresponding to the vapor temperature of the vacuum. Water, vapor, and total pressure are therefore in equilibrium. The most

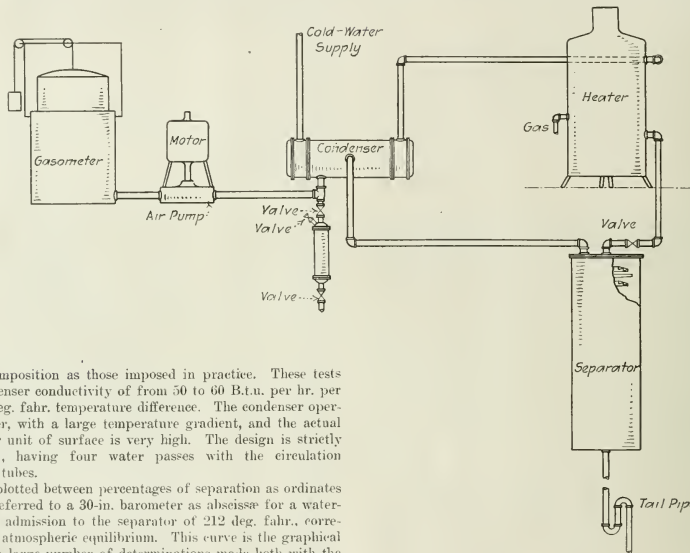

FIG. 1 LABORATORY SEPARATION EQUIPMENT

the same composition as those imposed in practice. These tests gave a condenser conductivity of from 50 to 60 B.t.u. per hr. per sq. ft. per deg. Fahr. temperature difference. The condenser operates, however, with a large temperature gradient, and the actual transfer per unit of surface is very high. The design is strictly conventional, having four water passes with the circulation through the tubes.

Fig. 3 is plotted between percentages of separation as ordinates and vacua referred to a 30-in. barometer as abscissae for a water-temperature admission to the separator of 212 deg. Fahr., corresponding to atmospheric equilibrium. This curve is the graphical average of a large number of determinations made both with the laboratory and the commercial-size apparatus. Percentage of separation is defined for the purposes of these curves as the ratio of the quantity of gases removed to that actually present in the raw water, and the calculations were made in terms of volume. Calculation in terms of weight would, however, have had identical values.

The mechanism of the separation appears to depend upon three factors: namely, the natural decrease of solubility with temperature, the mechanical agitation of boiling, and the reduction of pressure. The reduction of solubility with heating amounts roughly to 70 per cent of the volume at normal temperatures, and separation to this extent was arbitrarily credited to the heater.

Water at 212 deg. Fahr. injected suddenly into the region of vacuum of the separator has considerable heat available to the vacuum and boils with explosive violence at the expense of the heat of the liquid, behaving exactly as though it were superheated. Vapor bubbles form upon minute entrained air bubbles as nuclei, and in passing off into the region of reduced pressure mechanically take some portion of the dissolved air with them.

By far the major portion of the separation, particularly in the elimination of the final traces of dissolved gases, is accomplished by the reduction of partial pressure and represents a simple application of Henry's law. The water flows through the separator

logical conclusion to be deduced from this is that, with the continuous sweep of the wet, dense water vapor from the separator, the air component of the vapor pressure has been reduced by entrainment substantially to zero, and that the process has furnished a very simple and efficient means of securing such a reduction of pressure. Experiments by the writer have confirmed the results of other investigators that it is impossible to secure complete separation within a reasonable time by pressure reduction alone in excess of 80 per cent of saturation, provided the water is refrigerated to prevent vapor evolution. This is primarily a question of apparatus, since vacuum pumps of types which permit of this experiment are invariably of low volumetric capacity at extreme vacua.

It was found early in the experimental work that water in pipe lines and in small streams unpolluted by sewerage is likely to be supersaturated with air. It was accordingly necessary to analyze water both before and after entering the process to get the measure of the results accomplished. Entering water temperatures fell continuously within the range of 38 deg. Fahr. to 70 deg. Fahr., but did not in the least conform to solubility-table values of dissolved gases. It is significant of the physical phe-

nomena underlying the method that at low degrees of separation (70 to 95 per cent) the test results indicate a definite degree of separation rather than the reduction of dissolved gas content to a definite small value. At separation values much in excess of 95 per cent, the quantity of gases remaining is so exceedingly small that accuracy of testing is a limiting feature in extending such a conclusion into this range. It is the writer's frank opinion that the flat asymptotic portion of the curve in Fig. 3 represents complete separation of gases, but it is impossible to prove it.

Fig. 4 presents data on oxygen separation plotted as a function of separator vacuum with a constant separator temperature gradient of 22 deg. fahr., and illustrates the effect of variation of pressure. The separator temperature gradient of 22 deg. fahr. was selected as the minimum value that could give maximum separa-

equipment can be made sufficiently flexible to meet all conditions of application. Where a steam ejector is used, however, it is desirable to subdivide condensing capacity, using one section to condense the vapors withdrawn from the separator to relieve the ejector of the duty of evacuating them, and the other section to recover the heat of the ejector steam. The theory of the steam ejector seems best satisfied by the assumption of an entrainment and velocity compression of an inelastic fluid, making no concessions for the intrinsic energy of the fluid compressed, and a very slight one for differences of entrainment with variations in density. An ejector handling the vapor mixture from the separator under a 10-in. mercury vacuum has approximately five times the steam consumption of an ejector evacuating only the air. There are no moving parts in the apparatus except the float level control valves in heater and separator.

Careful tests were made upon the two heaters which at different times supplied the separator. The heaters were of a standard induction open-heater type, with spray pans for agitating the water in its passage through the steam. The vent openings, which were standard with the manufacturer, were freely connected to the atmosphere. Both of these heaters were able to deliver their rated capacity (300 and 1000 boiler hp.) of water with a 2-deg. fahr. temperature drop on atmospheric steam. Water was taken from below the water line of both of these heaters by a slow, large volume displacement into special apparatus and was tested for air without releasing the pressure or lowering the temperature. These tests gave reductions of dissolved air of only from 10 to 20 per cent, but when a similar sample was collected by rapid displacement in an open bottle, results indicated from 60 to 70 per cent at 212 deg. fahr. and a maximum of 78 per cent at 224 deg. fahr. Within this range of temperature, water within the 300-hp. heater viewed through a glass window in a blank-flanged connection against a submerged incandescent lamp bulb, appeared to be milky with entrained air bubbles. While any generalization from such meager data as these would be presumptuous, the writer cannot help but feel that from the standpoint of dissolved-air separation the heating of water from mixture with steam is an essentially different proposition from heating from a submerged and wetted source in the matter of temperature gradient within the body of the liquid. These conclusions apply specifically to a heater of the induction type, and probably would be very different for a "through" heater with its greater venting.

This work was undertaken as an industrial-research problem with the expectation that it would have two distinct fields of usefulness: the elimination of boiler and economizer corrosion in boiler plants, and of that of the entire distribution system in central-station heating, and the improvement of conductivity in surface condensation of steam. It developed in the course of experiments that it had additional merit in the removal of dissolved and half-combined carbon dioxide. The matter of corrosion has always received wide attention from the engineering profession and a vast amount of investigational work has been done on it. It was accordingly assumed at the beginning that a recapitulation of existing knowledge was all that was needed to establish the pernicious effect of dissolved oxygen. In the field of surface condensation and the removal of scale-forming materials, however, it was realized that direct experimental proof must be submitted to carry any conviction.

#### CORROSION

Of the gases dissolved in water, nitrogen is altogether inert, hydrogen is inert except in the ionic form, while oxygen and carbon dioxide are the agents producing boiler and economizer corrosion. Similarly, among the dissolved solids magnesium chloride and soluble nitrates are to be included. Some waters, dependent upon locality, contain hydrochloric acid, and are included in the same category. Irrespective of the direct agent, however, all cases of boiler or economizer corrosion are ultimately either those of oxygen oxidation or of electrolytic currents. The ionic notation is the best vehicle for explaining the mechanism of the oxidation process, and in the complete paper recourse is had

Fig. 2 INTEGRAL VERTICAL-UNIT COMMERCIAL INSTALLATION

tion. This curve is plotted in terms of dissolved oxygen because dissolved oxygen only was determined, the methods of testing for dissolved air being too inaccurate to apply over the major part of the range. It is, however, probably of equal applicability to dissolved air.

The actual operation of a separator equipment is altogether as simple and straightforward as it can conceivably be. At a constant vacuum and admission temperature the water delivered by the separator is in exact equilibrium with the vapor-pressure temperature of the vacuum, and the increase of pumping head is exactly measured by the pressure head corresponding to the vacuum. The amount of heat in the vapor mixture and the amount of condensed vapor to be handled by the condenser can be calculated from the heat drop in the separator, and is constant at any specified rating. The circulation ratio in the condenser, which handles all the supply water in its cooling circuit, is constant for all rates of flow. Neglecting radiation, heat losses are substantially zero. The arrangement of exhauster and condensing

thereto to demonstrate that dissolved oxygen and dissolved carbon dioxide, both of which are removed by the process, are responsible for the dangerous features of boiler and economizer corrosion: the former by destroying the inhibitive polarization and displacing the equilibria of the inevitable slight solution of iron in water; the latter by increasing the concentration of hydrogen iron and with it the initial tendency of the iron to dissolve.

Carbonic acid contributes to the acidity of boiler waters and, as a corollary, to the electrolytic action, and, being volatile, mingles with the steam. In this sense whatever portion of it that returns with the condensate is cyclic in its effects. From its ability to dissolve ferrous carbonate as ferrous bicarbonate it tends to concentrate all the products of pipe-line corrosion in heating systems in the boiler itself, and makes the apparent boiler corrosion much greater than it really is. Certainly it is a very undesirable constituent of boiler waters, but not nearly so dangerous as dissolved oxygen.

A high-pressure steam boiler is so complicated a chemical factory that there can be no general panacea for its ailments, but it is thought that the removal of dissolved oxygen and carbon dioxide is a decidedly effective step in the elimination of corrosion. Since it is a basic attack at the root of the evil, it will contribute to the success of all methods of eliminating corrosion which engineering experience has found good, but as long as boilers are made of iron and fed with water, some corrosion is inevitable. Boiler compounds, alkalinity, electric potentials, etc., are involved with such an infinitely variable condition of equilibria within the boiler that their success in practice can only be partial, while the effect of the removal of dissolved gases is aimed at the equilibria conditions themselves and is self-regulating.

The internal corrosion of economizer tubes is a phenomenon closely parallel with that of the corrosion of boilers. The corrosion here is more severe and localized and the corrosion products

FIG. 3 RELATION BETWEEN AIR SEPARATION AND VACUUM

more alarming to the eye, although this is due primarily to a superficial change in the water of crystallization of the resulting hydrated iron oxides. The increasing cost of coal is bound to increase the use of economizers, but unfortunately both the cast-iron and the steel-tube types are unfavorably regarded, the former because of its uncertain factor of safety and the latter from its liability to corrode. Necessity, however, has already developed the steel-tube economizer closely along the type of header and tube construction used in boilers, and economizer boiler units are now available which show a decided increase in evaporative efficiency and reduction of cost over straight boiler units. The removal of carbon dioxide and oxygen will undoubtedly prolong the life of cast-iron economizers greatly, and will make the installation of steel-tube economizers economically practical and conservative. On this basis the gas-removal process will have technical significance in the future greater than it has at present.

#### SCALE PRECIPITATION

Carbon dioxide exists in water as carbonic acid ( $H_2CO_3$ ), which is capable of combining with carbonates to form bicarbonates; thus,

The carbonates of calcium and magnesium are soluble in the proportions of 23 and 106 parts per million by weight as carbonates, or, in other words, in water free from carbon dioxide, but soluble as bicarbonates in any proportion in which they are apt to exist in natural waters. Bicarbonates of either of these elements are metastable and readily part with their carbonic acid under the conditions existing in the separation equipment, being reduced to carbonates and precipitated in excess of their solubility values. Sodium carbonate and bicarbonate are soluble in all proportions, although half-combined carbon dioxide is also removed.

The air-separation equipment has been tried out on two waters; one from the water mains of the city of Pittsburgh, which had been drawn through a filtration plant from the Allegheny River; the other from a small local stream that supplies the Jeannette,

FIG. 4 RELATION BETWEEN OXYGEN SEPARATION AND VACUUM

Pa., works of the Elliott Company. Both waters were from the same water shed and had the same general analysis.

	Allegheny City of Pittsburgh Parts per million	Surface Stream Jeannette, Pa. Parts per million
$CaCO_3$ .....	24.92	15.7
$CaSO_4$ .....	130.53	18.2
$MgSO_4$ .....	4.59	15.7

$Na_2SO_4$ .....	1.87	6.6
$FeSO_4$ .....	9.14	3.0
$Al_2O_3$ .....	19.07	18.3
$NaOH$ .....	4.94	0.0
Organic volatile .....	27.00	12.
Total .....	225.06	96.
Total as determined .....	214.0	87.

The effect of the process in eliminating calcium carbonate was initially discovered by the soap titration test of Clark on a cooled and decanted sample of water which had been put through the process. It was difficult, however, to determine the dilution of the water with exhaust steam in the heater, and results from the method were only indicative. Careful gravimetric tests over the period June 1 to November 1, 1919, supplemented by careful volumetric titrations with phenolphthalein and methyl orange indicators, gave a uniform series of results running from 18 to 25 parts per million of  $CaCO_3$ , which agreed closely with solubility values. While exhaust-steam dilution appeared also in these results, the reduction was greater than could possibly be accounted for by dilution, and agrees closely with solubility values. The water after passing through the separation process invariably gave a pink color with phenolphthalein, although it gave no coloration before, indicating thereby the elimination of free carbon dioxide. Technical boiler water analysis is, however, so much a matter of hypothesis that such results as the foregoing may be regarded as confirmatory but not conclusive.

Calcium carbonate precipitates out of the hot solution of the process as a colloid, which coagulates very rapidly into a flocculent precipitate and becomes granular by the time it arrives in the boiler, where it is deposited as sludge. Scale taken from the boilers during the operation of the separation equipment gave only traces of calcium carbonate, although the sludge from the bottom

of the boilers contained a sufficient amount of it to be effervescent when treated with acid. No trouble was ever experienced from sealing of the boiler feed lines.

#### SURFACE CONDENSATION

The surface condensation of steam involves three distinct physical steps: the conduction of heat through a definite thickness of metal—the tube wall; and two boundary conditions, the transfer of heat from a vapor to a metal, and the transfer of heat from a metal to a liquid. In the surface condenser this latter condition is dependent upon the velocity, viscosity and temperature of the cooling water and the laws of the heat transfer are not definitely understandable. The other boundary condition is complicated in practice because the area exposed to steam flow is surrounded by a rarefied air film so that in reality two heat transfers are involved: from the steam to the air film and from the air film to the metal surface. The elimination of this film of non-con-

tion, and at its operating speed had a volumetric capacity of 63.3 cu. ft. per min.

Vacuum was measured at the air-pump suction and at the nozzle, a special gage being made by welding a connection to the top of a U. S. Weather Bureau mercurial barometer. The air entering the top of the mercury column was chemically dried, the vacuum was never released, and the piping was all of copper tubing. This gage had a reading accuracy of 0.01 in. of mercury, and it is felt that the accuracy is consistent.

A thermometer well was inserted into the air-pump suction in the hope that it would furnish a check on the gage. The curious situation developed that, while a thermometer well drilled in a flange of the pipe wall which was insulated with hair felt maintained within 0.1 deg. Fahr. of the temperature of the vacuum, the thermometer well projecting into the pipe showed a temperature several degrees higher at extremely high vacuum (i. e., 0.01 to 0.05 in. of mercury of the theoretical absolute) and equaled the temperature of the pipe at lower vacuum. The only plausible explanation was that the air particles were carried along in the rarefied vapor stream with a translatory motion but with a pressure so close to zero that all sensible molecular vibratory motion had ceased.

The temperature of the condensate was measured by a thermometer well immediately below the exit from the condenser, mercury-filled and equipped with a certified thermometer reading to 0.1 deg. Fahr. With the centrifugal pump the condensate removal was continuous. Heat transfer was determined from the temperature rise and weight of cooling water. Cooling water was delivered under constant gravity head through a regulating valve, and after going through the condenser passed through a baffled weir box and over a 90-deg. weir. This weir was sharp-edged, cut from 1/2-in. brass plate and mounted against a rigid iron frame with a commercially plane surface.

A method of checking this heat transfer was adopted which is curious in that it was successful, although the apparent odds against it were rather high. Steam was admitted to the expansion valve on the condenser after having been throttled from boiler pressure to 85 lb. gage by an automatic reducing valve, and in its passage from the boiler to the reducing valve the quality was measured. The condensate for an entire test was weighed in a large weighing tank. The sealing water from the air pump was weighed, its temperature rise measured, the amount of condensed steam calculated, and the amount of heat withdrawn with the air-pump vapors determined. The expansion of the steam into the condenser was assumed as one of constant heat content. This obviously did not represent the actual nature of the expansion, yet it was difficult to conceive of an appreciable quantity of heat being lost in the process. This heat value of the steam was corrected for initial quality, heat withdrawn by the condensate and by the air-pump vapors, but no correction was applied for radiation from or to the condenser shell. From this calculation heat transfer was computed and compared with that obtained from cooling-water measurement. The agreement between these values is the part that is curious. In a total of 52 tests the maximum difference is 35 per cent, the agreement perfect in two instances, and the average difference 7 per cent. The conductivities varied from 129 to 949 B.t.u. per sq. ft. per hr. per deg. Fahr. difference in temperature.

In order to provide for as precise a comparison as possible between tests with air and those without air, a series of tests was run in which air was not extracted from the water before it entered the boiler, although it was heated up to atmospheric temperature in the open heater of the separation equipment. Air was not admitted directly into the condenser because no means of measuring the quantity admitted was known which would be of consistent accuracy with the remainder of the experiments. Such tests as either of these series are evidently not representative of operating conditions, in that they were performed upon a condenser of air-tightness far in excess of anything attained in commercial operation. They are an attempt toward an ideal condition of condensation, however, and are offered as being of specific interest because they apply to an actual condenser.

FIG. 5 RELATION BETWEEN BAROMETRIC PRESSURE MINUS VAPOR PRESSURE AND VACUUM

densable gas and the attainment of an ideal boundary condition is all that the air separation can possibly attain. It is to be expected that it will increase the conductivity by eliminating the resistance of the air film and increase the vacuum by reducing the partial vapor pressure; but the intricacy of the experimental data is very apt to obscure the simple physical fact involved.

In the experiments on surface condensation the boilers were fed with water which had been put through the air separation process and which was practically air free; and high-pressure steam was conducted to a cast-iron baffled cone bolted to the steam inlet of the condenser, expanded to condenser pressure, and allowed to enter the condenser with considerable velocity but no impingement. Two surface condensers of very dissimilar types were tested under these conditions. The first was of an antiquated type designed for engine service. The second was one furnished by the C. H. Wheeler Manufacturing Company after a design which had been built for the Bureau of Mines for experimental purposes, and was the type of unit that would ordinarily be furnished for a 100-kw. turbine. It consisted of 228 tubes, 5/8 in. O. D., No. 18 B. W. G., with an active length of 8 ft., arranged in three water passes; calculated area, 301.7 sq. ft. It was furnished with a steam baffle and air-pump suction baffle, and was without rain plates, steam lanes or differential spacing. It was equipped with a motor-driven centrifugal condensate pump with condensate-water-sealed glands, and a 16-in. by 18-in. Rotrex dry-vacuum pump. This pump was separately motor-driven at constant speed, was arranged for separate sealing water injection,

On account of the volume of the data of these tests, some 3400 tabular values, it is not practicable to publish the complete log in the present paper. However, a specimen log of two tests condensed to about one-third of its original volume is given in Table 1 for the use of those who wish to make a numerical comparison between the two groups, and the remainder of the data is presented in the form of curves, between such groupings of coordinates as are conventional in the representation of condenser tests.

It appears to be impossible to raise conductivity without recourse to methods that are freakish. Most of the heat transfer in the air-free tests took place in the upper tube banks; the transfer of heat was enormous, but without the additional refrigerating effect of the lower tubes it would have been impossible to secure

TABLE 1 SPECIMEN LOG OF TESTS (CONDENSED)

Date	Separated 8/23/17	With Air 8/23/17
Time, hours	1	1
Barometric pressure, inches Hg.	28.96	28.98
Condensate, lb.	2.988	3.201
Condensate, lb. per sq. ft. per hr.	10.31	10.31
Condensate temperature, deg. Fahr.	89.1	87.1
Temperature cooling in, deg. Fahr.	67.8	64.2
Temperature cooling out, deg. Fahr.	82.8	80.4
Heat rise, cooling, B.T.U.	14.96	16.16
Weight head, ft.	0.682	0.682
Weight volume, cu. ft. per min.	5.852	5.852
Specific weight, lb. per cu. ft.	62.20	62.23
Weight cooling, lb. per min.	3638	3640
Weight cooling, lb. per hr.	218,222	218,424
Total heat to cooling, B.T.U.	3,266,097	3,538,459
Mean temperature difference log. deg. Fahr.	76.7	73.6
Vacuum in condenser, inches Hg.	28.60	28.57
Temperature of vacuum, deg. Fahr.	89.5	90.2
Absolute pressure in condenser, lb. per sq. in.	1.40	1.43
Heat transfer, B.T.U. per sq. ft. per hr. per deg. Fahr.	846	706
Vapor pressure of condensate, inches Hg.	28.62	28.70
Cooling-water velocity, ft. per sec.	8.47	8.47
Cooling-water rate in temperature, deg. Fahr.	73	68

a satisfactory vacuum. With the necessary refrigerating area the apparent conductivity was decreased.

The following data are significant of the range covered by the tests as a whole:

	Maximum	Minimum
Condensation rate, lb. per sq. ft. per hr.	18.87	2.82
Cooling-water ratio	174.5	8.7
Cooling-water velocity, ft. per sec.	11.94	2.77
Cooling-water temperature, deg. Fahr.	90.5	35.0
Cooling-water rise in temperature, deg. Fahr.	122.5	6.8

Fig. 5 is plotted between barometer minus the vapor pressure of the condensate as ordinates and vacuum as abscissa, a solid line representing equilibrium being drawn thereon. The refrigerating effect is very decisively indicated. The condenser circulation was contrailow, three-pass, and in the air-free tests no transfer could be detected in the first pass. Simultaneously the vacuum drop in the condenser fell from 0.2 in. of mercury for 5000 lb. condensation per hour and 29-in. vacuum air to zero at all rates up to 5700 without air. Unfortunately these data were not systematically taken, since it was not known at the outset just where the advantages of air separation would appear. Ordinarily with steam-air mixtures and very efficient air removal from the condenser the phenomenon is exactly reversed, the maximum rise and the maximum transfer taking place in the lower tubes. It was possible by closing a valve in the air-pump suction to operate the condenser easily for an hour with a drop of 0.05 in. of vacuum at vacua as high as 29.06 in. When the valve was closed the condensate temperature immediately came into equilibrium with the vacuum. When, however, the loss of vacuum amounted to 0.1 in., the further drop was very rapid, amounting to a complete loss in about 10 minutes. The law of loss of vacuum was not definitely determined, but it was never a straight-line function of the time. Under the conditions of condensate removal there was never any opportunity for "drowned" tubes.

The tightness of the condenser was maintained by three methods: filling the steam space with water under pressure and watching for leaks; filling with compressed air under a pressure of about 10 lb. per sq. in. and painting with soap suds; and pump-down tests with a laboratory high-vacuum pump. If pump-down tests showed a leakage greater than 0.1 in. mercury per hour, tests were never performed. Loss of vacuum under pump-down

conditions was always a straight-line function of the time over a period of several hours. Curiously, however, tests on the condenser operating with air-free steam showed higher vacuum than it was possible to secure on pump-down tests, and the loss of vacuum in such operation followed an entirely different law.

Fig. 6, giving relation between condensate depression (temperature of the vacuum minus (temperature of the condensate) and conductivity, shows again and more pronouncedly than Fig. 5 the effect of refrigeration in the lower tube banks.

## CONCLUSIONS

A careful consideration of the data of these tests in all their phases has led the writer to the following conclusions, the basis for forming which he has unfortunately not been able to make altogether clear:

a A comparison between individual tests on air-free steam and steam with air which are sufficiently alike in the variable quantity values or which it has been possible to reduce to a satisfactory basis of comparison, indicates an increase in conductivity of about 20 per cent, figured upon the entire area of the condenser.

b It is possible to reduce the air component of the vapor pressure in a tight condenser to within an immeasurable amount of zero, and simultaneously eliminate all dead areas in the condenser due to air blanketing.

c The fundamental problem in condensation of air-free steam is not to conduct the heat but to get rid of it after it is conducted.

FIG. 6 RELATION BETWEEN CONDENSATE DEPRESSION AND CONDUCTIVITY

The economical limit of permissible hydraulic losses will limit conductivities to substantially the values that are used in commercial practice today.

d In the condensation of air-free steam two processes are involved: the actual condensation and the refrigeration of the liquid, which take place in different zones and are distinctively different processes. One process disposes of the heat and the other produces the vacuum, and each is therefore as indispensable as the other. In the zone of condensation heat transfers reach enormous values. In the zone of refrigeration both heat transfer and heat available are very low, and the conduction is from a liquid to a liquid. In this zone a very close spacing of tubes is permissible, and any change in design which would substitute water films for water droplets would be a constructive improvement. It is possible to isolate from the data of the tests the fact that the zone of condensation is limited at least to 30 per cent of the tube area, and the reduction of vacuum loss indicates it to be much less. The ratio of temperature rise between the different circulating-water passes is radically altered from operation with very slight amounts of air.

e From the radically different rates at which heat is transmitted in the different zones, it is impossible in tests on condensers of different types with air-free steam to arrive at any data from which to formulate or verify laws on the conduction of heat. Neither is it possible to apply such laws without an empirical assumption on the distribution of heat between the various tube banks. These tests, while they truly represent the condensation of air-free steam, contribute no information on numerical values of actual conductivities.

# A Stoker for Burning Eastern Coals

Particulars Regarding a Newly Developed Stoker of the Conveyor-Feed Type in Which Forced Draft is Employed and High Rates of Burning Are Obtained

By L. R. STOWE,<sup>1</sup> ST. LOUIS, MO.

*It is well known that the chief difficulty in burning eastern bituminous fuels on chain-grate stokers is due to the fact that they cake or coalesce under the arch, and thus prevent the entrance of air through the fuel bed and check combustion. As a result of two years of experimental work a stoker has been developed by the Laclede-Christy Clay Products Company which, it is claimed, may be used satisfactorily with eastern bituminous fuels. This stoker, which the author describes, is of the conveyor-feed type and operates with mechanical draft. High ignition temperatures are employed, the air supply is graduated from feeding end to discharge end, and the fire is thickened at the point of ash discharge, all of which is said to result in the prevention of caking, the assurance of a CO<sub>2</sub> content of from 10 to 12 per cent and an intimate mixture of air with the combustible gas. Further, rates of burning up to 60 lb. per sq. ft. of grate area per hour are obtained, as compared with the 25 to 35 lb. on chain grates, and the percentage of combustible in the ash is reduced 50 per cent.*

FOR the past two years the Laclede-Christy Clay Products Company has been experimenting on a new forced-draft stoker for use with the various kinds of fuel found in this country. The stoker used employs the conveyor method of feeding, i. e., progressively moving chain-grate conveying elements feed the coal through the furnace and discharge the refuse to the ashpit. Fig. 1 shows the test boiler and stoker.

The feature of the conveyor feed that commends its use is its handling of the fuel bed in a positive, definite fashion. By striking off the fuel evenly under a feed gate and then literally carrying it on through the furnace and over the point of ash discharge, this mechanism prevents in a large measure the evils of less positive feeding devices, namely, specifically uneven fires, balled-up spots, and immovable clinker formations. These advantages of conveyor feeding are very attractive to the stoker designer, and as a result of this and of the fact that the under-feeds have quite thoroughly demonstrated the great advantages of mechanical draft, many builders are now experimenting on and developing various forms of forced-draft conveyor-feed stokers. In fact, work in this direction characterizes the efforts of the stoker industry at the present time, and the following particulars regarding the experimental work of the Laclede-Christy Company and the results it has attained should therefore prove of timely interest.

For many years it has been quite clearly established that nearly every requirement of a successful stoker is lacking when burning caking fuels on chain grates with natural draft. The coal cakes almost immediately upon entering the furnace, high rates of burning cannot be secured, the combustible content of the ash is high, the admission of the air is not properly graduated to the requirements of the various stages of combustion, and maintenance of links is excessive. This is indeed a complete indictment, and with the sole exception that the automatic features are always in evidence, it may be said that the performance of chain grates on eastern bituminous coals violates every requirement of a successful stoker.

It is well known that the caking property of eastern coal is the most serious obstacle in the way of the successful use of this fuel on chain grates. In endeavoring to burn Pocahontas and similar coals it is observed that tarry oils flow through the fuel bed as a result of the application of heat at moderate tempera-

tures. It is further observed that the coal under the arch is caked or coalesced by these tarry oils, and forms a sticky blanket that prevents the entrance of air through the coal and hence checks combustion and heat generation under the arch.

In attempting to remedy this situation the most natural thing to do is to employ mechanical means to break up the caked fuel bed, which is the course almost invariably taken by the inventor. In fact, the idea is prevalent that "A mechanical agitation of the fuel bed, for the purpose of breaking up the coke, is necessary or advisable when burning eastern coals." So many statements have appeared similar to the one just quoted that mechanical engineers have come to accept it as a basic fact. The results obtained at the experimental plant, however, have disproved this

FIG. 1 THE TEST BOILER AND STOKER

contention and in doing so have made possible the application of conveyor feeding to the burning of eastern coals.

In the experiments with this new stoker the ignition temperatures are extremely high and at these temperatures considerable amounts of air are forced through the fuel bed, thus providing for the absorption of sufficient oxygen in a short time to destroy the initial caking tendency. Moreover, it is reasonable to suppose that these unusually high temperatures at the same time cause a quite different procedure in the destructive distillation than that which obtains with lower temperatures.

The absence of coke formation has almost as marked an influence on the last half of the fire as on that portion under the arch, because since coke is not formed in the distillation zone the cemented coke lumps cannot be present in the final stages of combustion. The individual pieces of coal retain their identity exactly the same as when Illinois coal is used, with the result that the fuel bed has the soft, incandescent and fluffy appearance

Abstract of a paper to be presented at the Spring Meeting, St. Louis, Mo., May 24 to 27, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

which every chain-grate fireman realizes means economy and high rates of burning. The absence of coke formation in the final stages of combustion will be mentioned again.

### THE NEW STOKER

A description of the final apparatus decided on is advisable at this point for the purpose of showing how the high initial temperatures are attained. Fig. 2 is a view of the grate surface, its general incline being 20 deg. The arrows indicated by *A* point to narrow chain-grate or conveying elements, about 4 in. wide and placed on 7-in. centers. In the intervening 3-in. spaces are placed stationary tuyeres indicated by arrows at *B*. At the lower end of the grate surface the tuyeres *B* terminate in short pivoted bars *C* which are made automatically to rise above, then drop below the surface of the conveyor chains. This action takes place slowly. *D* is a feed gate, adjustable to give various thicknesses of fire exactly as on a chain grate. Partly overhanging the vibrating bars *C* is the bridge wall *E*, shown cut away in the center. An ignition arch is shown at *F*. This latter provision conforms to chain-grate practice except that with the greater incline of the grate the arch is farther away from the fire. Fig. 3 shows a cross-sectional side elevation of the stoker and boiler and Fig. 4 details of the conveying elements marked *A* in Fig. 2.

FIG. 2 VIEW OF THE GRATE SURFACE AND FURNACE TESTED

Close study of chain-grate practice has revealed much in the art of building up high ignition temperatures. A great expanse of bridge wall extending from a point horizontal with the arch to or nearly to the fuel bed is known to be of utmost value in directing heat on to the incoming fuel. This is the surface indicated by *A* in Fig. 3. The steep incline of the stoker in question permits this dimension *A* to be greatly extended over that possible with the ordinary chain grate. Moreover, it exposes the fuel bed more directly to the intense heat reflected from the bridge wall and the flame in front of it.

The form of arch was also taken from chain-grate practice and its design and placement has, of course, contributed its part toward the building up of the high fuel-bed and ignition temperatures that play so important a part in preventing the eaking and ultimate coking of the fuel.

In view of the troubles known to exist with eastern fuels when using a stoker that conveys the fuel undisturbed into the furnace, the author deems it advisable to give a further description of the stoker in question in the light of what is required today in the economical burning of coal for the generation of steam, touching particularly on those features that have been prominently wrong with chain grates. The following outline presents the entire situation at a glance, and later in the paper each of the items therein is briefly touched upon.

### PRESENT-DAY REQUIREMENTS OF AN AUTOMATIC STOKER COMPARED WITH THE PERFORMANCE OF CHAIN-GRATE AND CONVEYOR-FEED STOKERS—EACH USING EASTERN COALS.

Requirements of the Present-Day Stoker	Results Obtained With Eastern Coals	
	With Chain Grates	With Conveyor-Feed Stoker Described
1 It should completely burn all combustible that arises from the grate and perform this task under the great handicap of using no more air than is required.	This fires spotted with up-standing coke result in excess air and low CO <sub>2</sub> due to the fact that the air supply is not graduated down to a minimum at the rear of the stoker and to influences attending the coking of the fuel bed.	Graduation of air supply and thickening of fire near point of ash discharge and prevention of coke assure a consistent 10 to 12 per cent. CO <sub>2</sub> content with positive assurance of an intimate mixture of air with combustible gas.
2 It should bring about low combustible in the ash.	Combustible in the ash from 30 to 50 per cent.	Combustible in the ash from 16 to 24 per cent.
3 It should burn coal at high rates of burning—not only to obtain high capacities but to widen the range of economical rates of burning as well, that great flexibility may be assured.	Rates of burning from 25 to 35 lb. of coal per sq. ft. of grate surface per hour.	Rates of burning up to 40 lb. of coal per sq. ft. of grate surface per hour.
4 It should be as nearly wholly automatic as possible in operation.	Successful in the matter of automatic operation.	Successful in the matter of automatic operation.
5 It should not entail unreasonable expense in the upkeep of the grate surface or of the furnace brickwork.	No unusual maintenance cost for furnace brickwork, but a very high one for grate links.	Use of mechanical draft imposes a more severe condition for furnace brickwork, requiring a higher grade of refractories, but maintenance of ironwork is not excessive—in fact, may be considered quite satisfactory.

It is of interest to note that the difficulties with chain-grates on eastern coal have been violations of the essential requirements of the modern stoker, so it is not surprising that the opinion prevails that success cannot be obtained with eastern coals using the conveyor feed.

### AIR DISTRIBUTION

It will be generally admitted that one of the prime considerations, if not indeed the most important, in requirement No. 1 above, is that each particle of combustible (whether solid, vapor, liquid or gas) as it leaves the grate shall be accompanied initially and primarily by its own quota of oxygen-giving air, and it will also be admitted that these combustible particles leave faster from some parts of the fuel bed than from others. The necessity of considering the most vital subject, air distribution, is therefore indicated.

Samples of the furnace gases from all parts of the fuel bed have been analyzed from time to time as succeeding designs of stokers have been put into use. A survey of these analyses pointed out that the greatest amount of air is required at the forward end of the stoker and that only a limited supply is advisable just in front of the point of ash discharge. The individual tuyeres are only 14 in. long and are made in several interchangeable patterns, differing only as to the percentage of their air space, which ranges from 2 per cent to 22 per cent. It is to be noted, therefore, that great latitude in the matter of air supply is possible for any stage of combustion in these experiments.

Table 1 shows the air-space distribution finally decided upon. This arrangement gives the most uniform condition of furnace gas thus far attained.

There is a rather gradual decrease in the amount of air space from the initial to the final stages of combustion between the two extremes indicated in the table. It is to be noted therefrom, more-

TABLE 1 AIR-SPACE DISTRIBUTION ADOPTED FOR CONVEYOR-FEED STOKER

Air Space in Each Element at Feeding End		Air space in Each Element at Discharge End	
Conveying elements.....	8 per cent	Conveying elements.....	8 per cent
Tuyere elements.....	22 per cent	Tuyere elements.....	2 per cent
8 per cent of 60 per cent. =	4.8 per cent	8 per cent of 60 per cent. =	4.8 per cent
22 per cent of 40 per cent. =	8.8 per cent	2 per cent of 40 per cent. =	0.8 per cent
Total air space.....	13.6 per cent	Total air space.....	5.6 per cent

Conveyor elements—about 60 per cent of total grate surface  
Tuyere elements—about 40 per cent of total grate surface.

over, that it has been found that more than twice as much air is required for the zone of destructive distillation as for the bed of well-spent fuel, and hence the advantage of graduating the air supply is readily apparent.

#### LOW COMBUSTIBLE IN THE ASH

One of the best ways of reducing combustible in the ash with the conveyor-feed type of stoker is to build up high ignition temperatures. In the initial stages, the coal burns from the top down, while during the latter stages the burning is reversed, the bottom of the fuel bed, where the air is richest in oxygen, being most active. The stronger or hotter the ignition temperatures, the quicker this reversal is effected, and if an early burning from the bottom up is established the combustible content of the ash will be materially decreased. The high ignition temperatures of the improved stoker have previously been referred to and their influence has unquestionably aided in reducing the combustible of the ash to a satisfactory amount.

With the caking and ultimate coking of eastern coals that occur with chain grates, the air breaks through the continuous mass of coke at the fissures or crazed places. The burning starts at these fissures and continues into the bed for its entire depth. This burning is at first quite rapid when the fissures are small, but as they increase in size the burning of the remaining coke slows down, due not only to the cooling influence of the bare spots but as well to the lessening intensity of the draft occasioned by the continual increase of the effective air openings. By reason of the original coked condition of the fuel bed, then, the fire in its final stages is characterized by bare spots and upstanding coke. To avoid exceedingly low CO, it is necessary to run these bare spots out of the furnace even though the spots of coke must be carried along with them. In other words, an effort to slow down the feed and burn the coke would result in a stack loss greater than the attending saving from burning the combustible from the ash.

With the coking of the fuel bed prevented and with each particle of coal preserving its identity in the last stages of combustion, the air filters through the innumerable interstices of the coal and causes the fuel bed to burn down evenly, giving that soft, intensive and highly luminous fuel bed that makes for high CO, in the gas and low combustible in the ash.

As to the retarding mechanism shown in Fig. 2, the short pivoted bars *C* in their lowest position allow the adjacent conveying elements to convey the ash from the furnace, but in their raised position they not only form an obstruction to the movement of the ash but raise the ash above the influence of the conveyor chains. The position of these bars with respect to the chains can be altered at the will of the operator to bring about any desired retarding influence.

The feeding at the upper end of the stoker is not affected by the retarding bars, and consequently while the ash is being positively held back of the point of discharge, additional ash-laden fuel is just as positively being conveyed toward the point of discharge by the positive feed from above. These actions result in a thickening of the fuel bed and in the squeezing out of any bare

spots that may have formed. Thus it is seen that not only is the combustible given a longer period of time in which to be completely burned, but the fuel bed is thickened so that the air entering through it may be effectively used.

It appears to the author that a particular virtue of mechanical draft lies in the burning of the combustible from the ash, for at the start of this process we are dealing with an extremely poor fuel of which the ash content may be considered to be as high as 60 per cent. It is with this in mind that the stoker in question has been so arranged that the full pressure of the wind box is made effective throughout the last stages of combustion. The experiments have been so conclusive on this point that if in further experiments it is decided to graduate the air pressure under the grate, the greatest pressure will be provided where the ash content is the highest. Of course, because of the relatively small amount of combustible in the fuel bed less air is required, so that, as explained above, the air spaces under this part of the fuel bed are materially smaller than elsewhere.

Four matters, then, are of importance in burning the combustible from the ash of eastern coals with the stoker in question.

FIG. 3 SECTIONAL ELEVATION OF BOILER AND STOKER

(The boiler has 2500 sq. ft. of heating surface and the stoker 40 sq. ft. of grate surface, giving a ratio of 62½ to 1.)

These are: (1) The influence of high ignition temperatures on the combustible content of the ash; (2) A fuel bed that may be said to be free-burning as compared to one characterized by a coking tendency; (3) The holding back of the ash and attending thickening of the fuel bed in the final stages of combustion; (4) Greater intensity of draft through the bed of nearly spent fuel.

#### HIGH RATES OF BURNING

Enough has already been said regarding the new stoker and its performance to make it evident that rates of burning with this type will be materially increased over those obtainable on chain grates using eastern coals with natural draft.

For instance, it is readily apparent that when the plastic, caking condition of the fuel bed is replaced by one that is free-burning and intensely active, the change will be very favorable to higher rates of burning. It is quite evident, too, that the application of forced draft will be an aid in this direction. It may be mentioned here that the chief means employed to obtain high CO, under forced draft have been (a) the air-distribution arrangement previously mentioned; (b) the retarding influence of the bars *C* together with the somewhat thicker depth of the general fuel bed over chain-grate practice; (c) the increased chemical activity of the fuel bed due to the higher fuel-bed temperatures;

and (d) the impinging of the air on the fuel bed through the employment of miniature air spaces.

#### AUTOMATIC OPERATION

Having satisfied the first three requirements, this stoker must justify the use of the word "automatic": that is, it must operate with the minimum of effort from the attendant. In this connection it is simply necessary to recall the basic principle of the conveyor-feed stoker—a positive feed from coal hopper to ashpit.

The only thing that interferes in the least with this entirely automatic and continuous operation is the clinker formation of the side walls. While this formation is no more serious than

effective in increasing the CO<sub>2</sub> and in raising the furnace temperatures, but it makes for a sluggish movement of the air over the faces of the links, thus reducing the cooling influence. It further causes the heat to penetrate down into the grate links instead of being carried briskly out of the furnace. An action of this kind, especially where stokers too large for the load are provided, produces in any stoker a condition under which no grate can permanently endure.

With a stoker of the type described the thickening up of the fuel bed, especially near the bridge-wall end, together with the high rates of burning, permits one with a relatively small area being employed. This same thicker fuel bed, too, may probably be considered the most important factor in protecting the links from the heat of the furnace.

The use of mechanical draft and small air spaces with the attending high velocity of air over the sides of the grates exerts a great cooling influence on the links even at moderate loads. Moreover, the links have been especially designed for this service. They are short, and much deeper than chain-grate links. They are free from any appreciable corrugations or flutings near the top face. Cooling veins extend deep down the sides of the links.

In the successive designs of stokers which led up to the one finally adopted, no one was operated for any appreciable time, but the links of the latest designs run so cool under both forced and natural draft that their low maintenance can easily be predicted. The maintenance of the tuyeres can only be determined by their extensive and prolonged use. But no deterioration of these or of the retarding bars has thus far been noticed and it is thought that the same influences that save the links will be more or less operative with the tuyeres, though due allowance must be made for the one important difference that the tuyeres remain continuously in use while the links as in the chain grate are used intermittently.

Regarding the maintenance of the brickwork, the higher rates of burning and the higher furnace temperatures of course impose more severe conditions. The maintenance due to mechanical draft, however, is not such as might at first thought be expected, for only a moderate air pressure (less than 2 in. water column) is used, and with the very small air openings occurring uninterruptedly across the entire width of the stoker, any impinging influence of the flame is lost quite near the surface of the fuel bed.

The problem of more severe furnace conditions has thus far been met by employing refractories of a higher grade. The side walls and bridge wall have been made with standard 9-in. shapes and the writer is advised that the higher refractoriness of the brick used is in part due to its higher percentage of alumina and its low content of fluxes.

Regarding the ignition arch, both the process and the mixture are new in stoker work. The material is highly refractory and porous and its performance under the harder usage bids fair to rival the ordinary arch maintenance in chain grates.

The essential points of this paper have been sufficiently marked to require no summary, but it may be said in closing that those connected with the experimental plant have derived considerable satisfaction in attaining the degree of success noted through the employment of such simple means.

In a lecture on Some Obscure Points in the Theory of the Internal-Combustion Engine, given recently at a meeting of the Junior Institution of Engineers, Prof. F. W. Burstall said that as regards the combustion of gases in a metallic envelope, it would appear that most of the phenomena connected with after-burning can be explained when the variation of the specific heat with temperature is taken into consideration, but there still remains doubt as to whether or not combustion is complete at the point of maximum temperature. He feels that nearly all the experimental work which has been done on the internal-combustion engine has a most serious drawback from the point of view of the student of thermodynamics, namely, the number of variable quantities involved is so great that it becomes almost impossible to deduce any exact laws from a series of experiments. (*The Engineer*, March 12, 1920.)

FIG. 4 DETAILS OF THE CONVEYING ELEMENTS MARKED "A" IN FIG. 2

with the chain grates, experiments are nevertheless under way in the experimental plant to minimize this evil.

As regards eastern coals, however, it may be of interest to note that they require less slicing of the side walls than do Illinois coals, probably because of the lower ash content and the higher fusing temperatures of the ash. Further, the eastern coals have a higher heat value and a greater firing stability than do Illinois coals, and consequently require less attention. And because of these advantages the firemen of the experimental plant much prefer on this new equipment eastern fuels to those of the Central West.

#### LOW MAINTENANCE

All of the factors relating to the actual burning of the coal have now been discussed and there remains only the consideration of the matter of low maintenance.

Excessive maintenance of chain grate links when using eastern coals may in part be ascribed to the uneven burning of the fuel bed at the rear of the grate and to the low ash of these fuels. These two conditions combine to lay bare and expose the grates to the heat of the furnace.

Further, in an effort to build up a high CO<sub>2</sub> content in the escaping gases and thus exclude the thief, too much air, the boiler dampers are apt to be partially closed. This procedure may be

# Locomotive Feedwater Heating

## Description of a New Type of Heater and a Discussion of the Advantages of Locomotive Feedwater Heating

By THOMAS C. McBRIDE,<sup>1</sup> PHILADELPHIA, PA.

*This paper describes a system of locomotive feedwater heating which makes use of the so-called open type of heater in which the exhaust steam comes into direct contact with the cold feedwater. The author describes the construction and operation of the heater and discusses the coal saving, water saving, and possibilities of increased capacity due to locomotive feedwater heating. These are dealt with first from a theoretical standpoint, and second from the practical standpoint, based upon the reports of actual tests. Tables and curves based on tests are presented and analyzed, and the paper is concluded with a discussion of the question as to whether the exhaust steam taken by the feedwater heater would cause trouble with the draft. From actual operating conditions the author states that "there was a surplus of exhaust steam left available for the draft."*

THE use of feedwater heaters on locomotives dates back to the beginning of the locomotive itself. There are records of the application of an open or injection type heater to a locomotive in England in 1827, and an English patent of 1828 describes a tubular heater for the same purpose. Ross Winans of Baltimore applied tubular heaters to two types of Baltimore & Ohio railroad locomotives in 1836. It is worthy of note that the desirability of the feedwater heater for the locomotive was recognized at these early dates, although it must be appreciated that the advantages possible at that time were proportionately greater than at the present time because of the low-steam pressure then in use.

There is much of interest in the history of locomotive feedwater heating in a paper, *Feedwater Heaters and Their Development*, by J. Snowden Bell, which was presented at the fiftieth annual meeting of the American Railway Master Mechanics Association, in June, 1918. Every conceivable type of heater and all possible sources of heat, even the hot ashes, seem to have been proposed or tried, and in view of the amount of study that has been given to the subject it seems rather remarkable that locomotive feedwater heating is not now in more general use. Possibly the reason lies partly in the fact that it is only in comparatively recent years that the essentials of heater performance and pump operation have been understood.

There are two possible sources in a locomotive from which otherwise waste heat may be obtained to heat the feedwater. These are: (a) the waste gases in the smokebox or stack and (b) the exhaust steam.

The exhaust-steam heater may be either of the open or injection type in which the exhaust steam comes into direct contact with the cold feedwater so that the water condensed from this exhaust steam is added to and mixed with this feedwater; or, of the closed or surface type in which the heat from the condensation of the exhaust steam passes to the feedwater through thin sheets of metal, generally in the form of thin brass tubes. Practically all of the development work to date that has been at all successful has considered only the surface type. There are a great many heaters of this type in service in Europe, but there are objections to it for locomotive use. It is a complex and delicate structure. It wastes the water condensed from the exhaust steam with its heat or raises complications as to saving it, and requires enough exhaust steam to heat all of the feedwater. On the other hand, the open or injection type of heater necessarily recovers both the water condensed from the exhaust steam and its heat so that both are returned direct to the boiler

with the water taken from the tender. Less water is therefore taken from the tender and less exhaust steam is required for the heating.

### DESCRIPTION OF A NEW TYPE OF HEATER

With these thoughts in mind, the author has devised a system of locomotive feedwater heating which makes use of a heater of the open type which is manufactured and marketed by the Worthington Pump and Machinery Corporation. The system follows marine practice in heaters of this type, and the pump and heater have been combined into a single unit which can be conveniently attached to the side of the locomotive boiler as is the practice with air-brake compressors. Fig. 1 shows a unit with a capacity of 60,000 lb. of feedwater per hour in service on a Mikado locomotive and Fig. 2 a sectional view of the heater and pump. In these illustrations the heater is shown at the left, the feed pump at the right.

FIG. 1. PUMP AND HEATER APPLIED TO MIKADO LOCOMOTIVE

The heater is a simple cast iron box, the upper part of which is supplied with exhaust steam taken from the locomotive through holes cut in the back of the cylinder saddle and a pipe which has in it a stop check valve and an oil separator, the latter having a small hole in it so that there is a continuous drip for the oil.

The pump is of the vertical type attached to the side of the heater by the various pipe connections. The steam cylinder of the pump is at the top, and it has two water cylinders clearly shown in the illustrations, both operated from the same piston rod. The water cylinder in the middle of the pump takes cold water from the tender and delivers it through a port in the side of the heater to a spray valve in the extreme top of the heater where it is sprayed into the exhaust steam that fills the top of the heater. This condenses as much of the exhaust steam as the water needs to heat it, and the mixture, dropping to the bottom of the heater, is taken by the other pump cylinder and delivered to the boiler through the usual check valve.

<sup>1</sup> Sales Manager, Worthington Pump and Machinery Corporation. Mem. Am.Soc.M.E.

Abstract of a paper to be presented at the Spring Meeting, St. Louis, Mo., May 24 to 27, 1920, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

The pump is driven by saturated steam taken from the locomotive boiler through a 1-in. steam pipe and controlled by a throttle valve in the cab within convenient reach of the engineer. The exhaust steam from the pump is led into the back of the stop check valve where it mixes with the exhaust steam from the locomotive and passes with it through the oil separator to the heater.

The adoption of the open heater for the locomotive may seem a radical step, but from this description it will be evident that no new elements are used. The heater itself is of a general type that has been in use in marine service for at least twenty years. The open heater with the oil separator to remove the oil from the exhaust steam before it enters the heater because of its merits has been almost universally adopted for stationary plants. One of these heater and pump units was thoroughly tested out on the locomotive test plant of the Pennsylvania Railroad at Altoona, Pa., in 1917 and has been in operation on road service since October, 1918. Three more units have been in operation for

FIG. 2 SECTION OF THE HEATER

approximately a year on pooled locomotives and have given no trouble other than the usual pump maintenance. Nothing has developed indicating that the open heater as a type is not well adapted to the locomotive and the coal and water savings have been so marked as to be evident to the crew.

#### ADVANTAGES OF LOCOMOTIVE FEEDWATER HEATING

It is not possible to make an exact general statement of the advantages to be obtained from locomotive feedwater heating because so much depends on the particular locomotive to which the heater is to be attached, the capacity at which it is worked, the temperature of the water in the tender, and the basis on which the advantages obtained are stated.

We are liable to base our notions as to the advantages of feedwater heating on the results obtained in stationary practice where the coal saving is very properly considered as equivalent to the reduction in the amount of heat necessary to evaporate the water because of the higher temperature at which the water is delivered to the boiler due to the heater. In the case of the locomotive, however, with its very complicated relations of the different operations that are going on and the very wide range of capacity through which the boiler is operated, there is generally a much greater coal saving than in stationary practice. Three factors enter into the final result. These are as follows:—

1. The reduction in the amount of heat required to evaporate the water in the boiler, which might be called the *heat saving due to the feedwater heater*.

2. The reduction in the amount of heat required results in a greater reduction in the amount of coal required because of the better efficiency of the boiler at the lower rate of combustion. These two factors give the *coal saving based on water evaporated*.
3. The exhaust steam taken by the heater from the exhaust ports of the locomotive reduces slightly the back pressure in the locomotive and should show some advantage. All three factors combined will give the *coal saving based on indicated horsepower*.

An analysis of these three factors will show the coal and water saving referred to the steam that is used in the locomotive cylinders, and therefore, the minimum saving since it does not include the saving in generating the steam used by the auxiliaries. It is necessary to make this analysis partly theoretical, assuming certain constant operating conditions in order that a fair comparison may be made of the effect of the heater on different locomotives and at different locomotive capacities. It can only apply to the coal burned while running since the heater can have no influence while standing or at terminals. The percentage of coal saving due to the heater, and to a lesser extent the percentage of water saving when based on ton miles, the month, or the year will be less than the percentage while running by an amount determined by the use made of the locomotives.

#### HEAT SAVING DUE TO FEEDWATER HEATER

The first factor, the heat saving, is determined by the amount the feedwater is heated by exhaust steam taken from the locomotive. This factor will evidently be greatest when the tender water temperature is low and when the exhaust steam pressure in the heater is highest, as this pressure determines the temperature to which the feedwater can be heated. This pressure will be highest when the locomotive is working hard, and when the exhaust steam for the heater is taken from that part of the steam valve chests or cylinder saddles where its pressure is greatest.

Test-plant results and actual daily operation on the road with superheated steam locomotives show that the feedwater heater described can be depended on to effect a reduction of at least 10 per cent in the summer time and 12 per cent in the winter time in the amount of heat required to evaporate the water and superheat the steam. This heat saving will not be constant at these figures but will vary with the capacity at which the locomotive is

Heat required, per cent.	87.0	89.25	87.81	89.95
Heat saving as compared to injector operation, per cent.	13.0	10.75	12.2	10.05

worked because the steam pressure in the heater determines the temperature to which the feedwater can be heated. These figures can, however, be conservatively accepted as representing average working conditions at which the greater part of the coal is burned.

The tabulation given in Table 1 is based on heating the feedwater to 215 deg. This is quite conservative as it has been found easily possible to obtain this temperature with this heater even with tender-water temperatures of 40 deg. and on locomotives worked at less than two-thirds of their maximum steaming capacity. The tabulation shows that greater heat saving is possible with saturated than with superheated steam locomotives; therefore the percentage of coal saving will be greater with saturated- than with superheated-steam locomotives.

From the tabulation it will also be noted that in the case of the feedwater heater for the locomotive, because of its comparison to injector operation, it is not possible to apply the usual short rule customary in stationary practice stating that a certain number of degrees of heating of the feedwater results in 1 per cent heat saving, but rather that it is more exact to state, assuming the conditions of the table, that in the saturated steam locomotive, after the first 23.8 or 23.2 deg. heating, each 11.9 or 11.6 deg. of heating represents 1 per cent heat saving, and that in the superheated steam locomotive after the first 22.3 or 21.8 deg. of heating each 12.8 or 12.5 deg. of heating represents 1 per cent heat saving, the first figures in each case applying with 40 deg. and the second figures with 70 deg. water temperature.

European practice, as far as the author is informed, involves the use of tubular heaters differing only in details of their construction and discharging to the track the water condensed from the exhaust steam in the heater, thus losing both this water and its heat, necessarily with some additional steam that must be blown through the heater to prevent it becoming air-bound. These locomotives require 2 per cent more water than when op-

eration. water saving is from 13.3 to 16.4 per cent respectively for the assumed summer and winter conditions as compared to injector operation.

#### COAL SAVING BASED ON WATER EVAPORATED

To combine these results with the second factor in order to obtain the coal saving based on water evaporated it is necessary to consider particular locomotives since the second factor involves the change in the efficiency of the boiler with varying boiler capacity. For this purpose the curves of Fig. 3 have been prepared. The curves on the left marked A are on the basis of 10 per cent heat saving; those on the right marked B on the basis of 12 per cent heat saving. The upper solid curves marked "Injector" are test plant results of a Consolidation, Atlantic, and Mikado type locomotive respectively and show the total amount of water evaporated per hour against dry coal fired. The dotted curves marked "Heater" for each of these three locomotives show the amount of water that would have been evaporated by the same amount of coal with a feedwater heater reducing by 10 per cent and 12 per cent respectively the amount of heat required to evaporate the water and superheat the steam. The vertical distances between the solid and dotted curves represent the amount of coal saved and these quantities are shown in the lower set of curves. This lower set of curves, therefore, shows the coal saving based on water evaporated due to the feedwater heater that follows a reduction of 10 per cent and 12 per cent respectively in the amount of heat necessary to evaporate the water and superheat the steam.

It would be difficult to credit this result were it not warranted theoretically by the second factor mentioned above, and had it not been confirmed in test plant results with a wide margin to spare. A study of the upper curves in connection with the lower curves of both figures will show that the very great coal saving possible is accompanied by an increase in steaming capacity due to the feedwater heater and that it should be possible to work the locomotive with the heater at greater steaming capacities than are possible with the injector, but how much greater would depend largely on the particular locomotive.

Referring to the lower set of curves of Fig. 3 and assuming that the consolidation locomotive would be operated normally at a steaming rate of say 25,000 lb. per hr., it is noted that the 10 and 12 per cent heat savings assumed as summer and winter conditions would result in 14 and 16.6 per cent coal savings, respectively. Assuming that the Atlantic type of locomotive would also normally be operated at a steaming rate of 25,000 lb. per hr., the coal saving would be 12.8 and 14.5 per cent respectively. Assuming that the Mikado locomotive is hand-fired and operated at a steaming rate of 37,500 lb. per hr., the coal saving would be 12 and 14.2 per cent, respectively.

On the other hand, it is altogether possible that advantage should be taken of the feedwater heater either in increased speed or increased hauling capacity, and the same amount of coal burned with it as would have been burned if the locomotive had been operated with the injector. In this case, the summer-time

10 per cent heat saving would result in a  $\frac{100}{100-10}$  per cent steaming capacity, or 11.1 per cent increase; and the 12 per cent heat saving would result in a  $\frac{100}{100-12}$  per cent steaming capacity, or an increase of 13.6 per cent. But as compared to injector operation of the first two factors as shown in Fig. 3, leading up to the Consolidation locomotive would be 15.5 and 19 per cent, in the Atlantic locomotive 13.3 and 15.5 per cent, and in the Mikado locomotive 13 and 15.3 per cent respectively.

The feedwater heater does not appear to as great advantage in the Mikado locomotive as in the other type locomotives because

FIG. 3 CURVES SHOWING THEORETICAL COAL SAVING BASED ON WATER EVAPORATION

erated with the injector because of the steam used by the feed pump and discharge to the track from 15 to 18 per cent of this with from 2.6 to 1.8 per cent of the heat of the saturated and 2.4 to 1.6 per cent of the heat of the superheated steam locomotive in the water alone for 40 and 70 deg. water respectively. There are a few surface heaters in operation on locomotives in this country in which this water is saved by pumping it back to the tender through filters to remove the oil, but in doing so approximately 80 per cent of its heat is lost by radiation from the tender. This loss of heat from the locomotive with the surface heater does not count directly against the coal saving since it is supplied by the exhaust steam, but it does count indirectly since it decreases the amount of exhaust steam left available for the draft. The open heater is more economical in the use of exhaust steam and leaves more available for the draft with the possibility of lower back pressure and saving because of this.

The locomotive with the open heater or the surface heater saving the water condensed from the exhaust steam requires the extra 2 per cent steam to operate the feed pump, but from 15 to 18 per cent of this 102 per cent is recovered, so that the net

it is not as fully loaded. If the Mikado locomotive was operated at a steaming rate of say 50,000 lb. per hr., the assumed 10 and 12 per cent heat saving would have resulted in a 15 and 17.3 per cent coal saving respectively, and if advantage had been taken of the feedwater heater for the increased capacity burning the same amount of coal as with the injector, the coal saving would have been 18 and 21.2 per cent respectively.

#### COAL SAVING BASED ON INDICATED HORSEPOWER

Any modification which the third factor makes in the combination of the first two factors as shown in Fig. 3, leading up to the coal saving per indicated horsepower, must be but slight and depend on the particular locomotive. Saturated steam locomotives should show a further gain of a few per cent from reduced back pressure. Test plant records show some reduction in this back pressure in superheated steam locomotives accompanied by a reduction in superheat and indicate that, at least until further tests are made, this factor should not be considered for superheated steam locomotives.

Table 2 and the curves of Fig. 4 are test-plant results of a Mikado locomotive, comparing its operation with the injector and

FIG. 4 CURVES SHOWING COAL SAVING BASED ON INDICATED HORSEPOWER

with the feedwater heater described in this paper. They show a coal-saving curve of the same general character, but slightly higher than the curve for the Mikado locomotive of Fig. 3-B, which is based on water evaporated, although the tests were made under practically identical operating conditions as to temperatures and pressures.

The coal-saving curve of Fig. 4 has been reproduced in Fig. 5, and a curve added showing the reduction in the amount of heat required to evaporate the water and superheat the steam because of the heater. The cross-hatched area below this curve shows the saving in heat due to the heater. The cross-hatched area above this curve shows the additional saving, presumably all due to the better efficiency of the boiler with the reduced amount of heat required from the fire because of the heat recovered by the heater.

#### EXHAUST STEAM AVAILABLE FOR THE DRAFT

Question has been raised as to whether the exhaust steam taken from the locomotive by the feedwater heater would cause trouble with the draft. This question could be analyzed from the partly theoretical curves of Fig. 3, but as actual operating conditions are of more interest, curves have been added to Fig. 5, showing the total exhaust steam taken by the heater and the exhaust steam taken from the exhaust ports of the locomotive. The distance between these two curves represents the exhaust steam furnished by the feed pump to the heater. It is noted that the

curve of exhaust steam taken from the exhaust port is below the curve of coal saving. The feedwater heater, therefore, reduced the amount of coal burned at a greater rate than it reduced the amount of exhaust steam, so that there was a surplus of exhaust steam left available for the draft, no necessity for reducing

TABLE 2 COAL SAVING AND INCREASE IN EFFICIENCY WITH FEEDWATER HEATER

the size of the blast nozzle and consequent possibility of reduced back pressure in the locomotive cylinders because of this heater. For instance, at 2000 i.h.p., the reduction in the amount of coal burned was 18 per cent, and in the amount of exhaust steam 12½ per cent. As compared to injector operation, 82 parts of coal had to be burned and 57½ parts of exhaust steam were left available for the draft to burn it.

#### CONCLUSIONS

The feedwater heater on the locomotive may be used to reduce the coal and water consumption working the locomotive at the same capacity as with the injector or to increase the capacity of the locomotive, or partly for both, as occasion demands. It will

FIG. 5 ANALYSIS OF COAL SAVING BASED ON INDICATED HORSEPOWER WITH EXHAUST STEAM LEFT AVAILABLE FOR DRAFT

save coal and water all the time, and permit of increased capacity when needed.

The feedwater heater might be considered as alternate to large size of locomotive boiler and grate as a means to coal economy,

# Efficiency of Natural Gas Used in Domestic Service

Results of Tests on Commercial Burners Under Kitchen Conditions, Showing Effect of Gas Pressure and Distance Between Burner and Vessel on the Efficiency

By ROBERT F. EARTHART,<sup>2</sup> COLUMBUS, OHIO

The following paper describes a series of efficiency tests on natural gas which the author made in the physics laboratory of Ohio State University. The operating conditions under which the tests were made were similar to those which commonly obtain in domestic service. Eight pounds of water were heated, in a granite-ware kettle, from the temperature of the tap to the boiling point. The definition of efficiency adopted is: heat units employed in raising temperature of water divided by total available heat units in gas consumed. The tests show that, under low-pressure conditions, an efficiency greater than 45 per cent can be secured when the burner is close to the vessel and that an equal efficiency can be obtained with the flame up to a distance of two inches from the vessel, under high-pressure conditions. It is further shown that with reasonable care in adjusting these distances the efficiency is independent of the rate of gas consumption and that under the varying conditions which now exist, it is advisable that the distance between burner and vessel should be between 1 and 1½ in. This will render operation possible under low pressures with fair efficiency and will lie within the range of maximum efficiencies which may be secured at moderate pressures and without undue sacrifice of time. A final experiment shows that a slight increase in efficiency is obtained by using an aluminum instead of a granite-ware container.

OF the three divisions of the natural gas industry: production, distribution and utilization, utilization now offers the most inviting field for improvement and conservation. The general topic to be studied is the relation between the thermal content and efficiency of a gas. The term "efficiency" as applied to the utilization of gas in the kitchen of the average home is a very indefinite term. Leaving out of account the operation of a furnace, the ordinary household processes are boiling, baking, frying, and perhaps ironing. In several of these it is impractical to formulate a rigorous definition of efficiency. In baking, the B.t.u. actually put into the loaves of bread should form the numerator of the efficiency fraction. The number of B.t.u. which must be expended to bring the oven to the proper temperature and the number radiated during the actual baking process cannot properly be regarded as units directed into performing useful work. The process of frying involves a similar difficulty in developing a satisfactory definition of efficiency.

The boiling process involves less difficulty. The intent, usually, is to direct a sufficient number of heat units against a vessel so that the liquid contained therein may be raised from room temperature to the boiling point. In formulating our particular definition for efficiency, only those heat units used in raising the temperature of water are regarded as performing useful work. The heat used in raising the temperature of the containing vessel is not reckoned as useful work; i. e., the water equivalent is neglected.

Among the factors which determine the efficiency of a particular gas are (1) the type of burner, (2) the pressure of the gas, (3) the size of the mixer, (4) the rate of flow of the gas, and (5) the distance from the burner to the bottom of the containing vessel. The one factor which seems to combine these is

the location of the tip of the flame with reference to the containing vessel. When the tip of the flame impinges on the bottom of the vessel, the various separate factors are so determined as to yield a maximum efficiency. The deviation from this best position produces considerable variation.

## METHODS AND APPARATUS USED IN TEST

In these tests, 8 lb. of water were placed in a granite-ware preserving kettle. The water was raised from the temperature at which it was drawn from the tap, to the boiling point. The vessel measured 8 in. across the bottom, weighed 2.03 lb. and was provided with a tin cover. A thermometer was suspended in the vessel, passing through a small hole located 1½ in. from the center of symmetry of the cover. The vessel was supported by an iron ring-stand touching it only at the periphery, so that there was no obstruction between the burner and the bottom of

FIG. 1. ARRANGEMENT OF APPARATUS FOR DETERMINING EFFICIENCY OF GAS

the vessel. The arrangement is shown in Fig. 1. The gas was metered through a Wright wet meter, the indicator of which made one complete revolution of the dial for 0.1 cu. ft. and could be read accurately to 0.001 cu. ft. During a test, the time of each passage of the pointer over the zero of the scale was accurately noted and recorded. The rise in temperature of the water in the vessel was noted at two-minute intervals up to within a few degrees of the boiling point and then, at one-minute intervals. These data could then be plotted and the curves extrapolated when changes in boiling point due to variation in atmospheric pressure sometimes made it desirable to compare exactly equal ranges in temperature. Plotting the gas-consumption curve and the temperature curve of the water made it possible to ascertain the exact amount of gas consumed during any given rise in temperature of the water. The meter having been accurately calibrated and the temperature and pressure of the gas observed, its volume was reduced to standard conditions, viz., 30 in. pressure at 60 deg. Fahr. The rise in temperature of the 8 lb. of water being observed, the number of B.t.u. per cu. ft. of gas developed was computed, this figure serving as the numerator of the efficiency fraction. The total B.t.u. content was determined by means of a constant-flow gas calorimeter manufactured by the American Meter Company and loaned by the Ohio State Utilities Commission for these tests. The gross B.t.u. content was determined; also the net B.t.u. content, which is the gross value less

the amount of heat given up by the product of combustion in condensing. The usual procedure was to run (1) a series of two tests with the granite kettle; (2) a series of three tests with the gas calorimeter; and (3) another test with the granite vessel.

Four types of burners, shown in Fig. 2, were used for these tests. All burners were selected because of their common use in widely distributed types of stoves and no appliances nor means of adjustment not ordinarily supplied as part of the equipment were used. Burners of types A and B were of the simplest pattern. The gas issued from them as small independent burnen flames of equal height. These simple burners where the envelop of the flame surface is flat, gave efficiencies a little higher than the other types. As has been stated, the essential feature for maximum efficiency is that the tips of the flames impinge on the

FIG. 2 TYPES OF BURNERS USED IN DETERMINING EFFICIENCY OF GAS

bottom of the vessel and this is best accomplished when the separate jets of burning gas are of the same height.

Twelve simple mixers which could be used on any of the burners were available. The largest of these corresponded with an opening made by a No. 28 B & S gage drill; the smallest, to a No. 60 drill. The latter is impractical for low pressures and the larger size may be used in a very wasteful manner at high pressures. In some cases a special mixing device was tried. This consisted of a mixer opening, back of which was a secondary mixer having six holes. Its only advantage is the possibility of securing a greater flow of gas under low-pressure conditions than could be obtained with the simple mixer. This advantage means flexibility of adjustment rather than efficiency.

In these tests no refined appliances were used to secure adjustments, but effort was made to utilize to the best advantage the air and gas adjustments provided as part of the regular equipment.

#### EFFECT ON EFFICIENCY AT VARYING DISTANCES, PRESSURES AND GAS CONSUMPTIONS

The results secured under a variety of conditions indicate that under low pressures an efficiency greater than 45 per cent can be secured. Equal efficiencies may be obtained up to a distance of 2 in. from burner to vessel if higher pressures are used and the rate of consumption is increased. This has a practical advantage because the operation can be performed more quickly with the same efficiency. Efficiency of this order, however, could not be secured when the distance between burner and vessel exceeded 2 in.

A bulletin published in May, 1918, by Mr. S. S. Wyer and Miss Edna White, called particular attention to the fact that a maximum efficiency could be obtained with short gas flames under low-pressure conditions. Results obtained by the writer under similar conditions confirm this point. In a report of the Research Committee of the Institute of Gas Engineers of England, published in the *Gas Journal*, October 29, 1918, it is stated that efficiency is independent of gas consumption within a considerable range,

provided the gas is properly aerated and proper flame contact is attained. Data upon which this conclusion is based were obtained on gas whose calorific value was about one-half that of the gas used in the present tests. The present experiments, however, are in agreement with this conclusion.

Some few measurements were made with the burner at a distance of  $\frac{1}{2}$  in. from the vessel. Operating difficulty at this distance was experienced, as the flame produced was unsteady and likely to flash out, being smothered by its burned gases, and unpleasant fumes resulting. The thermal condition seemed to be good notwithstanding the bad hygienic condition. An oversupply of gas with the burner at  $\frac{3}{4}$  in. gave rise to the same condition and considerable care in adjustment was required, especially when the vessel was cold.

FIG. 3 EFFECT OF CHANGING BURNER DISTANCE WITH CONSTANT LOW GAS PRESSURES

#### EFFECT OF LOW GAS PRESSURE

Tests were run, using the same common-size mixer throughout, to learn how low gas pressure affected efficiencies. When the pressure head falls below 0.3 in. of water, household operations are carried on with difficulty. At the start of the test, the pressure of the gas was reduced to 0.3 in. the burner set  $\frac{3}{4}$  in. from the bottom of the vessel and the mixer valve adjusted for maximum efficiency. The burner was then lowered in steps of  $\frac{1}{2}$  in., readings being taken at each step without additional adjustments. When the distance was increased to  $2\frac{1}{4}$  in. the water could not be

FIG. 4 EFFECT OF PRESSURE VARIATION WITH MIXER VALVE WIDE OPEN, BURNER DISTANCE CONSTANT

raised to the boiling point. Beyond a certain stage, radiation equaled input and no further rise in temperature could be obtained. At  $2\frac{1}{4}$  in. the maximum temperature was 207 deg. fahr. If we regard the heat used to raise the temperature of the water to 207 deg. fahr. as usefully employed, the efficiency was 19.8 per cent. At a distance of  $2\frac{3}{4}$  in. the maximum temperature attained was 197.5 deg. fahr. When we distort our definition of efficiency

### Head Resistance of Radiator Cores—Resistance Due to Nose Radiators—Streamline Casing for Free Air Radiators

**HEAD RESISTANCE DUE TO RADIATORS.** The present report consists of three papers, of which the first, by R. V. Kleinschmidt and S. R. Parsons, treats of the Head Resistance of Radiator Cores. The main conclusions arrived at are as follows:

The shape and size factors are insignificant for the range covered (8 by 8 in. to 16 by 16 in. and 12 by 24 in.), there being no perceptible variation in the resistance per square foot.

The effect of inclining the surface of the radiator to the air stream (yawing) is, in general, to increase the resistance considerably for angles up to at least 30 deg. to 45 deg. Cores of special construction vary greatly in this characteristic.

The horsepower absorbed by the radiator in being lifted and pushed through the air is high, being, at 100 m.p.h., roughly 5 per cent to 20 per cent or more of the total power developed by the engine. It thus appears that a small gain in radiator performance may be very appreciable at high speeds.

The investigation would indicate that a high head resistance is not in itself a detriment to a radiator if properly placed in the aeroplane. A radiator placed in the open air as between the planes or beside the fuselage must be of low head resistance. In the case of nose radiators the real limit is the frontal area which may be occupied. On the other hand, if the radiator is placed in the wings, head resistance is of little detriment.

A table giving the characteristics of various radiator cores and a table of comparisons of head resistance of radiator cores are given in the original article.

The second paper, comprising a preliminary report on Resistance Due to Nose Radiators, by R. V. Kleinschmidt, is based on wind-tunnel tests over model fuselages which show qualitatively that at any given plane speed the total resistance of a fuselage with the front nose radiator is increased by increasing the air flow through the radiator.

It would further appear that the resistance of a fuselage with streamline nose is increased more by removing the streamline nose and substituting a radiator than it is by adding an equivalent unobstructed radiator and retaining the streamline nose.

A brief report on the Effect of Streamline Casing for Free Air Radiators, by S. R. Parsons, would indicate that head resistance can be decreased very materially in this way, but the accompanying decrease in mass flow of air through the radiator and consequently in heat transfer nullifies the advantage gained, with the possible exception in the case of very high speeds. (*National Advisory Committee for Aeronautics, Report No. 61, 1920, Preprint from the Fifth Annual Report, 22 pp., illustrations, ep*)

**COMPARATIVE MERITS OF MAGNETO AND BATTERY IGNITION SYSTEM ON LIBERTY-12 AERO ENGINE.** Data of tests in which the Dixie magneto represented one system and the Delco the other system.

The engine was connected to an electric cradle dynamometer in the customary manner. Tests were first conducted to determine the difference in fouling of spark plugs when used with either of the two systems. To determine this the engine was run with each ignition system for one-half hour at idling speed, and then at one hour at normal speed under full throttle operation, allowing one gallon of lubricating oil to flow into the intake system during each run. To do this the center pet cock of each of the four intake manifolds was connected with the corresponding outlet from a calibrating container filled with lubricating oil, the amount of flow being regulated by means of a valve.

The results of tests appear to be as follows: When the engine was run at idling speeds, the plugs fouled equally, no matter what system of ignition was used. The difference in power output on these runs is accounted for by the fact that the run with the Delco system was made with the spark fully retarded, while the run with the Dixie system was made with the spark fully advanced. During the one-hour runs at full power none of the plugs ceased firing with either system, the oil merely burning on the plugs to form carbon. The resultant carbon deposits were about the same with either system. The power runs show that the magneto ignition gave a little more power both on the one-hour run and the run with set spark. To offset this, however, it should be noted that on the last power run with the battery ignition and spark set at each speed the power obtained was much higher than that which was obtained on any previous run, either with magneto or battery ignition. It is therefore concluded that spark-plug fouling and power output are the same for both systems, within the limits of experimental error. (*Air Service Information Circular, Engineering Division, Air Service, McCook Field, Feb. 13, 1920, vol. 1, no. 17, 2 pp., ec*)

**AERIAL TRANSPORT OF WOOLEN GOODS.** Owing to the congestion of traffic at Hull Docks and to the dockers' strike at Amsterdam, the transport of goods from the Midlands to Holland, which has been taking the preposterous time of from six to eight weeks, has, for the meantime, become quite impossible. For this reason Messrs. Heaton's (Leeds), Limited, who do considerable business with Holland in ladies' clothing, decided to despatch by aeroplane a quantity of goods which they were anxious to deliver in Holland in time for the spring season. A Blackburn "Kangaroo" commercial aeroplane was therefore chartered, from the North Sea Aerial and General Transport Company, of Leeds, to convey 22 packages, with an aggregate weight of over 1000 lb. to Amsterdam. The machine was loaded at Brough aerodrome, near Hull, on Friday, March 12, and proceeded to Lympne, near

Folkestone, for examination by the air-port authorities and thence to Soesterberg aerodrome at Amsterdam, where it arrived safely on the following day. The Dutch customs authorities arranged to examine the cargo immediately on its arrival, so that the packages could be despatched to their final destinations with little or no delay. The machine was expected to return with a valuable cargo of dyes of a class urgently required in Yorkshire and Lancashire. It is hardly necessary to point out that the commercial value of the service would be greatly augmented if the visit to Lympe for customs examinations could be avoided. Lympe is, at present, the only recognized point of departure for Continental aerial traffic, and this fact is obviously a severe handicap on aircraft traveling from the northern countries to Holland and the Baltic. Evidently the traffic would be greatly facilitated by Government recognition of an air station on the North Sea coast, since a direct flight across the North Sea could be made in half the flying time, and in much less than half the total time, owing to the fact that the long southward diversion renders a night's stay at Lympe unavoidable. (*Engineering*, vol. 109, no. 2828, March 12, 1920, p. 344, g).

## CORROSION (See Engineering Materials)

### ECONOMICS

AMERICAN COMPETITION WITH BRITISH TRADES. This subject is discussed in *The Engineer* (London) in an editorial entitled: The Question of American Competition.

The writer calls attention to the sales efforts of American concerns in Europe; such as the fact that a leading American locomotive firm is alleged to have sent a representative to The Hague where he offered to quote prices not only on locomotives and other railroad equipment but also on all kinds of machinery, including machinery for treating sugar, rubber, coffee and coconuts in tropical countries.

On the other hand, it is stated that in the calendar year of 1919 American exports decreased while imports increased, the reduction being due to the fall in the quantity of semi-finished steel sent out of the country for the account of the Allied nations. The imports increased through purchases of scrap and pig iron. (The statistics refer, of course, exclusively to the metal and machinery trades.)

If the American statistics are contrasted with those for Great Britain, it is found that the British exports showed a recovery for the first year after the end of active hostilities. The exports rose from 1,618,000 tons in 1918 to 2,254,000 tons in 1919, being an advance of 636,000 tons, giving a net balance of 360,000 tons to the advantage of Great Britain. The figures in the case of machinery are also hopeful for Britain, although a strict comparison between the latter and the United States cannot be made. The British exports advanced in tonnage by 65 per cent as compared with the preceding year.

As regards the future, it is stated that American steel and machinery makers have secured a great hold on international markets under the abnormal circumstances of a world-wide war, and thereby have become enormously enriched. Furthermore, though peace prevails, the conditions throughout the world have not become normal and probably will not do so before several years have elapsed. There is a great international demand for iron, steel and different classes of machinery in various countries and it is believed that Great Britain will obtain its fair share of this world trade as in former years. In fact, figures appear to show that it has already been able to make a fresh and favorable start in the resumption of its former position in the markets of the world. Though the present high prices tend to facilitate American competition in external markets, except where the rate of exchange exercises an unfavorable influence upon prospective customers, nevertheless the amount of work available in the world is so enormous that international competition for the purpose of securing it should be inconsiderable for a long time to come. (*The Engineer*, vol. 129, no. 3349, Mar. 5, 1920, pp. 249-250, g)

## ENGINEERING MATERIALS

### Classification of Types of Corrosion of Brass

THE CORROSION OF CONDENSER TUBES. Abstract of the Fifth Report of the Corrosion Committee of the Institute of Metals, confined to the corrosion of condenser tubes, mainly 70:30 brass.

The first section deals with what has been called the diagnosis of condenser-tube corrosion and describes the procedure to be followed in withdrawing and preparing a tube for examination, and also symptoms indicating corrosion. Conditions existing within the plant, in particular, water supply, are stated to be of great importance.

The second section is devoted to a consideration of certain features in the structure of condenser tubes and attention is directed to the presence on the tubes of a surface layer consisting of structureless, highly distorted metal. This layer has a greater resistance to corrosion than the underlying crystalline metal so that whenever this layer is penetrated corrosion will proceed at an increased rate. The thickness of this layer is usually of the order of 0.01 mm. (0.00039 in.) and indications have been obtained that its composition may be different from that of the underlying metal.

In the third section the five main types of brass-condenser-tube corrosion are considered in detail. These types are:

*Type I, General Thinning.* This may be considered as an accelerated form of the complete corrosion which normally occurs in saline solutions, the tube being gradually and uniformly reduced in thickness. Rapid general thinning, however, is essentially a fresh-water phenomenon and is usually associated with the presence of free acid in the water supply. Tests have shown that even with dilute solutions of hydrochloric acid such as 3 parts in 100,000, in six weeks tubes had lost from 3 to 4 per cent in thickness. Proper neutralization of the acid is an effective remedy for this trouble. It is difficult, however, to detect the acid, especially if it appears in the water supply only intermittently.

*Type II, Deposit Attack.* This results in pitting and is based on the following chemical reaction. In the presence of sodium-chloride solution the cuprous oxide formed on a brass surface gradually changes to cuprous chloride. This latter is usually swept out of a condenser tube by the circulating water, but under various conditions may adhere at different parts of the tube surface. When such adherence has occurred, conditions allow of the further gradual change of the insoluble cuprous chloride under the influence of oxygen to soluble cuprous chloride and cuprous oxide. The action of cupric chloride solution on brass is very rapid and, for example, a piece of brass tube 2 in. long, placed in a strong cupric chloride solution at ordinary temperature, was completely disintegrated and partially replaced by a pseudomorph in copper in two days.

*Type III, Dezincification.* In dezincification, in the case of a 70:30 brass, true parting of zinc and copper does not occur but the so-called residual copper is always redeposited copper. There is therefore no real but only apparent dezincification. The layer type which is characterized by the disintegration of the brass tube and redeposition of copper over large areas has been found to occur with both salt and fresh water, and several ways in which it may occur are indicated.

*Type IV, Plug or Local Dezincification.* This type of corrosion always proceeds beneath a deposit and is stimulated by the presence of foreign bodies. It differs, however, in many ways from Type II. So far as is known, it occurs only in sea water and is always associated with appearing quite salt consisting of colloidal zinc oxyhydroxide, also containing some carbonate. The dezincifying action is thought to be due to a small concentration of hydrochloric acid contained within the colloidal white salt. The behavior of different tubes is not always the same and the reason for it is not clear.

*Type V, Waterline Attack.* In brass tubes only partially immersed in sea water increased corrosion takes place not at the waterline itself but above it—sometimes as high as 2 cm. (say,

0.8 in.) above the air-sea-water surface. Further, the attack is not uniform but is concentrated at areas where salt deposits have formed. This type of attack may occur at the inlet end of the tube and is prevented by eddying effects from being swept away by the water flow.

The fourth section of the report contains an account of preliminary work on the electrolytic protection of condenser tubes. The particular question investigated was that of the efficiency of electrolytic protection in preventing deposit attack. It is considered that a small electric current slows down, but does not necessarily inhibit corrosion. By raising the current density sufficiently it is possible to prevent all corrosion, even in a cupric chloride solution, but the current must be quite heavy. (Official Abstract of the Fifth Report on Corrosion to the Corrosion Committee of the Institute of Metals, *cp. The Engineer*, vol. 129, no. 3350, Mar. 12, 1920, pp. 267-268, *ca*)

### No Fissures in Old Rails

OLD RAILS. A report by W. C. Cushing, Chief Engineer of Maintenance, Pennsylvania Lines West of Pittsburgh, gives an interesting sidelight on the cause of the appearance of transverse fissures.

This report covers an investigation of rails which had been in service from 10 to 45 years; some of the oldest were of wrought iron, others rolled from iron and steel pile, while others 10 to 25 years old were of bessemer steel.

In the old wrought-iron rails, head strains corresponding to 24,000 to 27,000 lb. per sq. in. in compression were found, which appeared the more serious because the material had a low elastic limit, 26,670 to 48,760 lb. per sq. in. The piled rails showed maximum head strains of 24,000 lb. per sq. in., and the elastic limit of the material ranged from 33,700 to 58,830 lb. per sq. in. Still higher internal strains, however, were found in steel rails that had been in service 20 to 25 years, several measurements of 36,000 to 33,000 lb. per sq. in. being made, as against elastic limits of 46,500 to 58,450 lb. per sq. in. These high values of permanent strain were measured at the surface of the head and on the side opposite the gage side in nearly every case. One abnormal result was a reading of 57,000 lb. per sq. in., tensile stress, in the flange of an 85-lb. rail that had been in service nearly 20 years (from 1888 to 1917); Mr. Cushing calls this "extraordinary and inexplicable."

From a knowledge of the service to which these rails were submitted, one would expect to find them filled with transverse fissures. In fact, rails adjacent to them and undergoing precisely the same condition of service had been found to contain such fissures, which would indicate that the difference in the behavior of the two classes of rails must be sought in the process of manufacture. (Report No. 84 to the Rail Committee of the American Railway Engineering Association, abstracted through *Engineering News-Record*, vol. 84, no. 11, March 11, 1920, p. 527, *g*)

THE EFFECT OF KILN DRYING ON THE STRENGTH OF AEROPLANE WOODS. T. R. C. Wilson. This paper is one of a series of monographs contributed by the Forest Products Laboratory, maintained at Madison, Wis., by the Forest Service, U. S. Department of Agriculture, in cooperation with the University of Wisconsin.

It embodies the data of a series of tests which included 26 species of wood, approximately 100 kiln runs and over 100,000 mechanical tests.

These tests were made the basis of the specification (Signal Corps No. 20500) for the general kiln-drying process for aeroplane stock (now with some slight modification specification 20500-A of the Bureau of Aircraft Production).

The general conclusions of the tests reached are:

1 That wood may have its strength properties, particularly toughness or resistance to shock, quite seriously damaged without any visible evidence of such damage. Hence, appearance of the

material cannot, where maximum strength is essential, be accepted as the sole basis of judgment of the effect of a drying process on wood.

2 That the effect of a given process is not the same on all species of wood.

3 That apparently a given process may be entirely safe for some but quite detrimental to other material of a species.

4 That proper kiln drying produces material equal in all strength properties to that resulting from air drying under the most favorable conditions.

5 That specification 20500-A of the Bureau of Aircraft Production (Table 1 or 2 as specified) can in most cases be expected to produce material fully equal to air-dried.

6 That best results (with respect to strength properties) on Douglas fir will result from the use of somewhat milder drying conditions than those laid down in Specification 20500-A (Table 1). Table 2 of this specification (temperatures 105 deg. Fahr. initial to 135 deg. Fahr. final and relative humidities 85 per cent initial to 40 per cent final) is recommended for drying Douglas fir.

7 That in some species there is apparently no relation between drying temperatures up to 180 deg. Fahr. and the strength properties of the dry material. Such a conclusion, however, needs further confirmation, and temperatures higher than those of Specification 20500-A have not been recommended.

This work has been done under the necessity of getting results as quickly as possible and with the primary object of checking the safety of the general kiln-drying specifications when applied to the drying of airplane lumber on a commercial scale, together with the more or less incidental object of ascertaining if conditions adapted to more rapid drying could be used. Under these circumstances it has not been possible to investigate the subject in the fundamental way which it merits. Completion of the work already begun is contemplated and it is hoped to be able later to carry out experiments to determine the effect of the various factors involved, both separately and in combination, and to ascertain the maximum temperature and minimum humidity that can be safely applied at any stage of the drying process. It is hoped also to carry on comprehensive investigations of the closely related subject of the bending of wood, for the purpose of determining the steaming or other processes best adapted to successful bending and to secure more accurate knowledge of the effect of such processes on the strength of the wood.

An interesting part of the table is the discussion of kiln drying as it affects the various species of woods. The methods used in the tests and the kilns are illustrated in the original article. (*National Advisory Committee for Aeronautics*, Report No. 68, 1920, preprint from the Fifth Annual Report, 69 pp., 22 figs. and 9 plates, *ep*)

REINFORCING BARS FOR CONCRETE. Discussion at the annual convention of the American Railway Engineering Association at Chicago in March, 1920.

Specific prohibition of twisted bars for the reinforcement of concrete, as provided in the masonry committee's specifications, met with some objection. Hot-twisted bars are dangerous, according to T. L. Condon, while Mr. Condon and Prof. A. N. Talbot (Mem.Am.Soc.M.E.) agreed that cold-twisted bars give no advantage over plain or deformed bars commensurate with the extra cost of the twisted bar. A suggestion that the twisting is in itself a test of the good quality of the steel was characterized by Mr. Condon as "salesman's talk." A proposal to limit the prohibition of hot-twisted bars was voted down.

Copper-plated bars, copper-alloy bars and a rough enamel coating for bars were suggested by the committee on electricity for use in reinforcing concrete subject to electrolytic action. This was accepted as information without discussion. It was pointed out that in reinforced-concrete ships protection has been based upon density and richness of concrete, and high quality of materials and workmanship, while experiments have been made with non-metallic waterproofing paints. (Abstracted through *Engineering News-Record*, vol. 84, no. 13, March 25, 1920, p. 615, *g*)

## GAS TURBINES

Holzwarth Gas Turbine, Thyssen Type; Large Compression and Power Output, Nozzle Design, Blade Design, Electrolytic Iron for Blades; Steam-Turbine Practice Applied to Gas-Turbine Design

DEVELOPMENT OF THE HOLZWARTH GAS TURBINE SINCE 1914, Hans Holzwarth. In 1914, a few months before the beginning of the war, tests were started on a 1000-hp. vertical gas turbine built by the firm of Thyssen & Co., in Mülheim (Ruhr). These

FIG. 1 THERMAL EFFICIENCY OF THE HOLZWARTH GAS TURBINE (ASSUMED TO BE FREE FROM LOSSES) AS A FUNCTION OF THE CHARGE PRESSURE PREVIOUS TO THE EXPLOSION (PRODUCER-GAS FUEL OF HEAT VALUE 500 KG-CAL. PER CU. M.; TEMPERATURE OF MIXTURE, 77 DEG. CENT.

FIG. 2 SPECIFIC OUTPUT OF THE HOLZWARTH GAS TURBINE (ASSUMED TO BE FREE FROM LOSSES) AS A FUNCTION OF THE CHARGE PRESSURE PREVIOUS TO THE EXPLOSION FOR VARIOUS HEAT VALUES OF THE MIXTURE

tests were discontinued during the war, but were started over again in 1918. The Thyssen turbine does not differ in external appearance from the gas turbine previously built by the author at Mannheim, but differs from it in several particulars of design.

**Higher Charge and Explosion Pressures.** These were adopted to increase the output per cubic unit of chamber capacity and the

thermal efficiency. The average explosion pressure for continuous operation was raised to from 12 to 14 atmos. abs. as compared with 5 to 6 atmos. abs. of the Mannheim turbine.

There is fundamentally nothing in the way of raising this pressure still higher by increasing the charge pressure above 2.3 atmos. abs. The curves of Figs. 1 and 2 show the influence of the charge pressure and explosion pressure on the efficiency and specific output of the turbine.

**Reduction of the Period of Expansion.** The shorter the time taken by expansion the less the loss of heat to the chamber and nozzle walls, and the greater the amount of heat transformed into kinetic energy, and hence the greater the efficiency. At present the duration of the period of expansion in the gas turbine is around 0.1 sec. In large gas engines running at 90 r.p.m. the expansion lasts about 0.33 sec., while in aircraft engines, in which the heat consumption is not materially inferior to that in Diesel engines, it is 0.02 sec. at 1500 r.p.m. Fundamentally there is nothing to prevent reducing the expansion period in the gas turbine still more. To do this, however, the nozzle cross-section must be increased, and this in turn leads to an increase in the length of the turbine blades and in flow resistances.

FIG. 3 TOTAL EFFICIENCY (AS MEASURED ON THE WHEEL PERIPHERY) AS A FUNCTION OF THE POWER OUTPUT AT THE WHEEL IN THE HOLZWARTH GAS TURBINE

**Changes in the Shape of Blades and Blade Fastenings.** Decrease in the period of expansion provides an increase in pressure on the blades. Furthermore, unlike what takes place in steam turbines, the jet in explosion turbines acts intermittently for short periods, and is of the character of a blow. Because of this the blade shapes and fastenings used, for example, in Curtis turbines would not be satisfactory. New blades, therefore, had to be developed which were planned to withstand the added stresses much better.

As regards the material of the blades, many kinds of alloyed and unalloyed hard and soft steels were tested, with rather unsatisfactory results, and finally a soft electrolytic iron was adopted. With proper heat treatment blades of this iron proved to be very satisfactory for use in gas turbines. Table 1 shows the physical properties of this material from tests made in the testing laboratory of the Technical High School at Stuttgart.

While blades made out of harder or alloyed steels rapidly show changes in the structure of the metal, cracks and fissures, electrolytic iron in gas-turbine blades appears to be quite capable of withstanding wear and also resistant against surface corrosion and erosion, provided, however, no substantial amounts of wet steam or water are present in the gases of combustion.

**Nozzle Shapes.** DeLaval nozzles and nozzles with parallel exit walls were tested as well as several other shapes. The advantage of nozzles with parallel walls, which lies in their offering a greater

cross-section of exit, is counterbalanced by an increase in the deflection of the jet, and on the whole it was found that steam-turbine experience applies within reason to the design of gas turbines. The most satisfactory results were obtained with DeLaval nozzles with minimum possible angle of exit, just as in steam-turbine practice.

Practical experience has confirmed theoretical expectations to the effect that the reduction of heat gradient during the expansion does not materially affect the efficiency of the gas-turbine nozzles and blading. For example, if the instantaneous maximum jet velocity at the beginning of expansion is in the neighborhood of 1500 m. per sec., more than 95 per cent of the mechanical energy of the gases of combustion is available at the wheel up to the time when the jet velocity decreases to about 1000 m. per sec. This

TABLE 1 PHYSICAL PROPERTIES OF ELECTROLYTIC IRON USED FOR GAS-TURBINE BLADES

		Tested at	
		Room temperature	450 deg. cent.
Yield Point.....	kg. per sq. cm.	4204	1975
Breaking Load.....	kg. per sq. cm.	3185	2675
Elongation.....	Per cent	27.2	50.2
Contracting.....	Per cent	73	88.4

means that more than 95 per cent of the energy is available at jet velocities varying 19 per cent either way from the average jet velocity for which the nozzle and blading have been designed. Practical experience confirms these theoretical considerations. Time after time useful efficiencies of about 55 per cent (i. e.,

FIG. 4 TOTAL HEAT SUPPLIED AS A FUNCTION OF THE POWER OUTPUT AT THE WHEEL OF THE HOLZWARTH GAS TURBINE

about 55 per cent of the output attainable in a gas turbine free from all losses) have been indicated on the periphery of the wheel.

In steam-turbine practice the upper and lower limits in the heat-drop process are determined on one hand by the initial pressure and temperature of the steam, and on the other hand by the vacuum in the condenser. Furthermore, the peripheral velocity of the rotor is also predetermined, and all that the designer can do is to rearrange the stages in one way or another. In gas turbines the lower limit of the heat drop is predetermined and for practical purposes so are the peripheral velocity and number of stages. On the other hand, however, the designer is free to vary the upper limit of the heat drop, and through this the important ratio  $\frac{\text{jet velocity}}{\text{peripheral velocity}}$  without materially affecting thereby the thermal efficiency of the turbine.

*Change in Nozzle Valves.* The employment of higher charge

pressures and the increase in the cross-section of the nozzles required some changes in the design of the nozzle valves, which are described in a very general manner.

*Tests.* The tests were carried out in the presence of various railroad officials in December 1919. The fuel used was coke-oven gas with a heat content of 3860 kg.-cal. per cu. m. (432 B.t.u. per cu. ft.). The turbine was driving a dynamo delivering current to a water rheostat. The main test lasted four hours and gave the results shown in Table 2.

TABLE 2 DATA OF TESTS OF HOLZWARTH-THYSEN GAS TURBINE

	1	2	3	4
Gas consumption, reduced to 0 deg. cent., and 760 mm. mercury pressure, cbm. per hour.....	300	400	550	630
Heat supplied, cal. per hour.....	1,150,000	1,530,000	2,110,000	2,415,000
Power output at wheel N-umf, hp.....	70	251	724	984
Heat consumption, kcal. per hp.-hour.....	16,430	6,090	2,915	2,450
Efficiency $\eta_{umf}$ , per cent.....	3.9	19.4	21.8	26

Figs. 3 and 4 give the amounts of heat delivered to the turbine per hour, and the efficiency  $\eta_{umf}$  refers to the power output  $N_{umf}$  delivered by the wheel. The work consumed in compressing the blast air and gas amounted to about 5.7 per cent of the exhaust heat. If the efficiency of the compressor be assumed to be 70 per cent, of the condenser steam turbine 18 per cent and utilization of exhaust heat 60 per cent, then the total efficiency for the exhaust-heat plant and the blower system is  $0.70 \times 0.18 \times 0.60 = 7.6$  per cent, in which case the power consumption for the blowers can be well taken care of by exhaust heat.

*Construction.* Gas turbines of the horizontal type appear to be preferable in several important ways to vertical turbines, and it

FIG. 5 HOLZWARTH OIL-FUEL GAS TURBINE, 500 HP. AT 3000 R. P. M.

is intended in the future to build only horizontal gas turbines. Fig. 5 shows the general outlines of a 500-hp. oil-fuel gas turbine now under construction to run at 3000 r.p.m. and drive a direct-current generator. The blower and exciter are built in on the same base as the main engine, and directly connected thereto is the exhaust-fuel-heated boiler delivering steam for the blowers. This installation is to go to the Prussian Railway Administration. The same article gives an illustration of a 12,000-kw. gas turbine, which seems, however, to be as yet only in the design stage.

It may be added that during the war there were several rumors of a gas turbine of extremely high efficiency having been developed by the Augsburg-Nuremberg Machine Company. In fact, it was stated that such a turbine was to be applied to drive an aeroplane. Thus far no information has become available to confirm the truth of these rumors. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 64, no. 9, Feb. 28, 1920, pp. 197-201, 14 figs., d.1)

## HYDRAULIC MACHINERY

Balanced Hydraulic Valve for Hydraulic Recoil and  
Recuperator Gears for Gun Carriages—Hydraulic-  
Valve Construction for Minimum Leakage

**BALANCED HYDRAULIC VALVE.** As a result of experience during the recent war in connection with hydraulic recoil and the recuperator gear for gun carriages, in which construction and design finally reached a stage when hydraulic pressure could be maintained in a group of cylinders for several weeks at a stretch with a loss of less than 5 lb. pressure. Mr. Pearson of the Erith Works, Vickers, Ltd., has designed the hydraulic valve illustrated in Fig. 6.

The chief points about this valve are that it has been designed to eliminate leakage at the moving parts, and that it is balanced both at the inlet and exhaust ends. Ease of effecting inspections or renewals has been also a main consideration.

FIG. 6 BALANCED HYDRAULIC VALVE NOTABLE FOR ITS VERY SMALL LEAKAGE

The body of the valve is cut from a rectangular block of steel and bored out to take valve bushes; inside these bushes works the valve itself. In Fig. 6-A the valve is shown with the connection from the machine in communication with the exhaust. In Fig. 6-B the position of the valve cuts off the machine both from the pressure inlet and exhaust, maintaining therefore pressure on the machine and keeping it stationary. In Fig. 6-C the valve is shown putting the machine connection in communication with the pressure inlet. It will be noticed that the inlet valve is tubular, and constructed with two series of ports *C* and *D* (Fig. 6-B and C). The pressure inlet connects with the space surrounding this valve, and when in the position shown in Fig. 6-C the pressure supply is put through to the machine by way of these ports, the set *C* acting as inlets and *D* as outlets to the machine connection. At the exhaust end the ports are in the bushing, and not the valve. In the position, Fig. 6-C, with the supply and machine coupled up, the exhaust-valve head is beyond the exhaust ports in the bush, and the exhaust is cut off. In Fig. 6-A,

showing the machine in connection with the exhaust, the valve head is near the open end of the bush, and the ports of the latter are uncovered, allowing connection via the interior of the sleeve, to the exhaust pipe. In Fig. 6-B, both connections from the inlet and to the exhaust are blocked. The pressure valve works in a chamber fitted with hydraulic rubber cup packings held apart by a bulb-headed spacing tube of frame, the sides of which are cut away. The exhaust sleeve is held in place and packed also with hydraulic rubber. The exhaust-valve heads are fitted with rubber packings pressed down on to the bulb-headed rings. The rubbers used in this valve are of a special composition, which thoroughly proved its great durability and efficiency in connection with gun carriages throughout the war. They are far superior to the ordinary leathers used in connection with hydraulic installations. The pressure packings and frame, and the exhaust sleeve and packings are held in place by their respective covers, which are fastened to the body by four studs and nuts. It will thus be seen that all parts may be quickly removed for cleaning and inspection; in fact, this can be accomplished and the parts re-

placed in less than 5 min., or in about 10 min. if new rubbers are required. The pipe connections can be bored and fitted to different sides as convenient and two or more valves can be coupled for combination working. It will be noticed that the ring packings are arranged so as to be more effective in preventing leakage. A small hole is drilled through the exhaust-end cover so that the double-headed piston exhaust valve shall be in equilibrium. The control lever can be easily moved by hand, and as the valve is balanced in all positions, will remain in whatever position it is placed.

In addition to the illustrations reproduced in this abstract the article gives two half-tones, one showing a general view of the valve and the other a view with the control lever dismantled and also showing the interior components and links for the lever. The whole is an interesting illustration of a minor mechanical detail developed to a very high stage of perfection under the stress of war demands. (*Engineering*, vol. 109, no. 2826, Feb. 27, 1920, pp. 281-282, *d*)

## IGNITION ((See Aeronautics))

## INTERNAL-COMBUSTION ENGINES (See also Aeronautics, Gas Turbines, Motor-Car Engineering)

BERGUND ORIGINAL SURFACE-IGNITION-TYPE ENGINE. Description of an engine now built in Sweden but which, it is stated, is likely to be introduced soon into the American market. Its design does not essentially differ from that of similar engines now known.

Fig. 7 shows a section. The cycle is as follows: Fuel oil is injected by the pump into the hot-bulb "T" via the injection nozzle H immediately before the piston reaches top center, and is sprayed on to the surface of the projecting surface V, which is heated when starting by transmission of heat from the double-flipped disk I, which is made red-hot by the blow lamp R. After the engine has been running a short time, the blow lamp is ex-

FIG. 7 BERGUND ORIGINAL SURFACE-IGNITION-TYPE ENGINE

tinguished and the projection R and the ignition plate are kept hot by the temperature of combustion. It will be noticed that both the hot bulb and cylinder head are watercooled.

The projecting piece V has a double duty as the fuel is sprayed on it at an acute angle in an almost solid stream, and is split by it into fine particles. And, in order to avoid chance of misfire at light loads, the flipped ignition disk V, termed the light-load ignition surface, is fitted just above it, and this enables the engine to run for long periods without load, or without the use of the blow-torch.

Fuel is fed to the injector by the pump A which is actuated by a cam on the governor. The governor regulates the position of the cam in such a manner that the stroke of the pump is suited to the load of the engine, hence the quantity of the fuel being varied. Before entering the cylinder, the fuel oil is passed through to separate filters, one of which may be taken out and cleansed while the engine is working. All troubles from the choking-up of the fuel-oil valves and the nozzle are obviated by this arrangement. (*Motorship*, vol. 5, no. 4, April, 1920, pp. 324-326, 13 figs., d)

CALCULATION OF LOW-PRESSURE INDICATOR DIAGRAMS, E. C. Kemble. The investigation deals with the theoretical study of the pressure variations in an internal-combustion engine cylinder during the low-pressure part of the cycle.

The method of calculation is based on certain assumptions

which are all to be regarded as rough approximations to the truth, such that it is believed that their adoption does not introduce any material errors.

In order to apply the method, it is necessary that pressures in the intake and exhaust manifolds at points adjacent to the valves and the effective clear valve openings shall be known functions of the time. By the effective clear opening of a valve is meant the product of the minimum sectional area of the passage through the valve and the coefficient of efflux.

The use of the method is of course restricted by the above requirements, since the manifold pressures are usually not known, but to a certain extent the actual varying pressure may be replaced by its average value which will give results that are interesting though not strictly correct quantitatively.

The subject of the value of the coefficients of efflux is discussed in considerable detail, the author being inclined to the opinion that the coefficients for steady flow should not differ very greatly from those applicable to intermittent flow obtained in practice, provided that the pressure used in making the calculations are those actually existing at points close to the valves.

Differential equations for the rate of change of the pressure in the cylinder during the exhaust and suction strokes are set up and a method for the graphic integration of these equations is indicated. Efflux coefficients taken from experimental data are used in the application of the theory to a typical motor and a theoretical low-pressure indicator diagram for this motor is obtained.

It is also stated that a method of computing theoretical low-spring diagrams has been developed which is capable of further development and refinements not justified by the experimental data now available. At present the absolute values deduced from the theory cannot be relied on, but future experiments may show how to modify the theory so that it will give quantitatively correct values. (*National Committee for Aeronautics*, Report No 50, Preprint from the Fifth Annual Report, 13 pp., 7 figs., tA)

## MACHINE TOOLS

## Attachment Converting Ordinary Lathe into Relieving Lathe

RELIEVING ATTACHMENT FOR LATHES. It is usually considered to be uneconomical to make milling cutters and other small tools in a general engineering shop, but occasions arise when it is desirable to do so.

All the equipment necessary to make such tools is usually available in shops, but difficulty arises in connection with the work of backing off or relieving the teeth of the cutters. The teeth can, of course, be formed by milling with special cutters, but the ordinary shop cannot have all the cutters required for different shapes and sizes of tools. A relieving lathe which might be employed is likewise an expensive tool of very little general utility and it would not pay to have one to take care of an occasional odd job.

From this point of view the attachment described here and built by Milton, Ltd., London, is of interest. It is intended to take care of just the kind of job that can usually be done only on a relieving lathe or by means of special tools.

Drawings, Fig. 8, A to E, illustrate the construction of the attachment. It is mounted on a gibbed plate which is screwed on to a lathe saddle. Into this plate is fitted a steel casting having a hole through which the work passes, or the arbor on which the work is mounted between the centers of the lathe. There are also two oscillating tool posts carrying tools which can operate simultaneously on the front and back of the work, though for relieving the front tool only is employed. Provision is made for adjusting the tools in a vertical direction to allow for any alteration in height which may have been introduced by grinding, likewise for the transverse adjustment of the tools. The tools themselves fit in slots in the tool posts and are each clamped in position by a bolt and nut.

The tool posts are rocked by means of two eccentrics mounted

on a central shaft passing through the upper part of the main casting as shown at *B*. These eccentrics, which are connected to the tool posts by means of short links shown at *A*, are set at an angle of 180 deg., so that angular motion of the shaft will cause both the tool posts to advance into or recede from the work together. Mounted loosely on the opposite end of the central shaft bearing is a gear wheel, and on a sleeve extending from the boss of this wheel is screwed a ratchet-toothed cam seen in the figure at *A* and *D*. The cam is driven from the nose of the lathe by means of a shaft having two universal joints. The cam rotates at the same speed and in the same direction as the work and must have the same number of teeth as the tool being relieved. The actual diameter of the cam and the shape of the teeth are immaterial, but the teeth may be formed with feather edges.

bell-crank lever is communicated to the central shaft, and also, through the eccentrics, to the tool posts. Two short springs fitted between projections on the forked parts of the tool posts and the main casting are provided in order to take up any lost motion due to wear of the links, etc.

It will be obvious that the position of the block in the segmental groove determines the magnitude of the angular oscillations of the central shaft, and consequently those of the tool posts, so that, by adjusting the block, the amount of relief can be varied at will quite independently of the shape of the cam. The actual amount of relief is indicated by a scale engraved on the arm of the bell-crank lever, as shown at *D*, the figures giving the amount of relief in millimeters. The only other feature of the mechanism now remaining to be explained is the

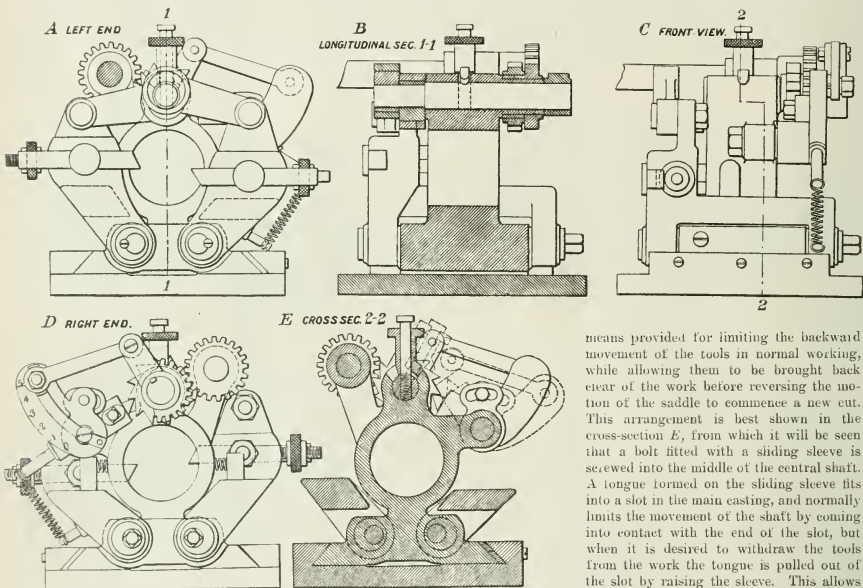

FIG. 8. MILTON RELIEVING ATTACHMENT FOR LATHES

Reamers and cutters in which the teeth are unequally spaced can be relieved by means of the attachment, but in such case the teeth of the cam must, of course, be spaced to correspond with those of the work.

Referring now to *D*, it will be noticed that the teeth of the cam engage with an adjustable pawl mounted on one arm of a bell-crank lever, which is pivoted on the main casting. As the cam rotates in anti-clockwise direction the arm of the bell-crank lever will be pulled downward until the pawl escapes from the tooth of the cam, when it will be pulled up into engagement with the next tooth by the action of a light helical spring seen in both illustrations. The combined effect of the cam and spring is thus to impart an oscillating motion to the bell-crank lever. On the other arm of the latter is formed a segmental groove, and in this groove a block, to which a short link is pivoted, can be clamped in any position. The other end of the link is connected to an arm keyed on to a central shaft, above referred to, and in this way the oscillating motion of the

means provided for limiting the backward movement of the tools in normal working, while allowing them to be brought back clear of the work before reversing the motion of the saddle to commence a new cut. This arrangement is best shown in the cross-section *E*, from which it will be seen that a bolt fitted with a sliding sleeve is screwed into the middle of the central shaft. A tongue formed on the sliding sleeve fits into a slot in the main casting, and normally limits the movement of the shaft by coming into contact with the end of the slot, but when it is desired to withdraw the tools from the work the tongue is pulled out of the slot by raising the sleeve. This allows the spring attached to the bell-crank lever to pull the latter back into the position indicated by the dotted lines in *E*. In this

position the tools will be quite clear of the work and the pawl clear of the cam; the lathe can then be reversed without altering the adjustment of the tools in the tool holders. This is a great advantage when relieving screwed hobs, and is also convenient for ordinary screwing without relief.

An important advantage of the pivoting tool holder in comparison with the horizontal slide of the ordinary relieving lathe, is that, in the former, the tools can be adjusted so that the cutting angle remains constant at all parts of the cut, and consequently greater cutting efficiency is attained and a tool with much less clearance can be used. That it is necessary to tilt the tool for this purpose will be obvious when it is remembered that the normal relief to the curve at the cutting edge of the tooth being formed coincides with the radius of the plain cylindrical blank, since no metal is removed from this part of the tooth, whereas, at the inner end of the curve, the normal is inclined by an amount depending upon the amount of relief. In an ordinary relieving lathe, in which the tool moves horizontally, no allow-

ance is made for this feature, and the cutting angle may therefore vary by 15 deg., or 20 deg. from one end of the relief curve to the other. Another advantage of the pivoted tool holder is that the friction is considerably less than that of a sliding holder, and consequently a greater proportion of the power supplied is available for the cut in the former system. It is also pointed out that the fact that the tool holder is operated from a point well above the tool gives great rigidity in cutting.

By illustrations and descriptions the original article shows the large variety of work which can be done by means of this attachment. (*Engineering*, vol. 109, no. 2828, Mar. 12, 1920, pp. 345-346 and 348, 11 figs., d)

## MARINE ENGINEERING

### Largest and Fastest Battle Cruiser Afloat in Any Navy

**BRITISH BATTLE CRUISER "HOOD."** Some data of the new battle cruiser *Hood*, built by John Brown & Co., Clydebank, which is said to mark the close of a period in naval history. The ship was intended to be one of a group of four, but is the only one to reach completion and is today the greatest unit afloat in any navy in existence.

The *Hood* was built under conditions of unusual difficulty. The builders were furnished with sketches of preliminary design in April, 1916, and the ship was launched on August 22, 1918, a highly creditable performance considering that the first keel plate was not laid until September, 1916.

In many features the ship heralds a new departure. The difference in structure that strikes the eye first (as compared with the existing battle cruisers) lies in the "bulge" or "blister" which secures the ship against effective attack by a torpedo. This blister surrounds the main hull of the ship, and has been carefully proportioned in order to reduce to a minimum the additional resistance it causes.

The use of the blister involved many interesting problems of design. Thus, the subdivisional bulkheads have been so arranged that the energy of an external explosion is absorbed at the spot, thus preventing the piercing of the main hull should the outer hull be blown in by the explosion.

The armor has been disposed so as to provide a protection against shell fire to the vitals of the ship. The deck over the magazines is 3 in. thick. The side armor is fitted in three tiers, the lowest of which is 12 in. thick amidships, tapering to 6 in. and 5 in. forward and aft. Above the main 12-in. plate the middle and upper tiers are respectively 7 in. and 5 in. thick, while the conning-tower armor is 11 in. in thickness.

The main armament of the ship consists of eight 15-in. guns, all on the middle line. Each pair of guns is mounted in an armored barbette. The barbette armor is 12 in. thick. The gun shields are 15 in. thick in front and 11 in. thick at the sides.

The secondary armament consists of twelve 5.5-in. guns, five of which are mounted on each side of the vessel on the forecastle deck, the remaining two being mounted on the top of the superstructure. All these 5.5-in. guns are protected by gun shields forming an integral part of the mounting. In addition there are four 4-in. anti-aircraft guns also mounted on the superstructure.

The propelling machinery comprises four distinct sets, each driving one shaft, arranged in three engine rooms. The turbines are of the Brown-Curtis type and each set of machinery consists of compound ahead turbines driving the propeller shafting through single reduction gearing. For use at cruising speeds a cruising turbine of the Brown-Curtis type is provided. This has a separate casing and can, at will, be connected to, or disconnected from, the main high-pressure turbine shaft by suitable clutches. At cruising speed this turbine is operated in series with the high-pressure and low-pressure turbines of the set.

The reverse turbine is fitted with the low-pressure casing and rotates in a vacuum when the ship is running ahead. Each of the four sets of machinery is complete in itself with its own condenser and auxiliaries and can be used independently.

Each high-pressure ahead turbine rotor consists of ten wheels,

of which the first and second are velocity-compounded having two rows of blades each, and the remainder are simple impulse wheels. Each low-pressure ahead-turbine rotor consists of eight wheels, of the simple impulse type. Each cruising-turbine rotor has four velocity-compounded wheels with three rows of blades on the first wheel and two rows on each of the others. The astern turbine for each shaft is incorporated in the low-pressure ahead-turbine casing and consists of two velocity-compounded wheels, each carrying three rows of blades.

The turbine casings are of cast iron with the nozzle-control-valve seatings cast in the body. The rotor spindles are of forged steel, having a tensile strength of 34 tons to 38 tons per sq. in. The wheels are of forged steel, of similar quality, and phosphor bronze has been used for the blades, which are of the usual impulse type. The blades have dovetailed roots, and the tips of the blades are supported by phosphor-bronze shrouding. The diaphragms are of cast iron, with the nozzle blades of nickel steel (about 3½ per cent nickel) cast in. The diaphragms in the cruising turbines and the first diaphragm in the high-pressure turbines are solid, the remainder of the diaphragms in the high-pressure turbine, and those in the low-pressure turbines, being split. The spindle is made steamtight where it passes through the diaphragms by segmental serrated brass rings, kept up to their work by garter copper-coated steel springs in the cruising and the first diaphragm of the high-pressure turbines, and by sherardized coach springs in the other diaphragms of the high-pressure and in the low-pressure turbines. The glands are packed, as is usual in Brown-Curtis turbines, with carbon rings made in segments and held in position by springs. The high-pressure ahead forward-end gland has eight carbon rings, the after end five, the low-pressure ahead four rings and the astern turbine four rings. The cruising turbine is fitted with five rings in each of the glands.

The turbines are designed to develop a total horsepower of 144,000 with about 210 lb. pressure in the control chest and 28 in. vacuum in the condensers. Steam is supplied by 24 Yarrow-type small-tube boilers burning oil fuel and located in four compartments. The working pressure is 235 lb. per sq. in. and the heating surface per boiler 7290 sq. ft.

The original article is illustrated by a number of plates giving an idea of the stupendous size of the unit itself and its various details. (*Engineering*, vol. 109, no. 2830, Mar. 26, 1920, pp. 397-399 and 4 pp. of plates, 12 figs., d,d)

## MILITARY ENGINEERING (See Hydraulic Machinery)

### MEASURING INSTRUMENTS

**THE SIGNALING PYROMETER, R. P. BROWN.** The ordinary pyrometer which either indicates on a temperature scale or records the temperature on a chart is satisfactory where the operators are capable of reading the temperature scale or understand the movement of the pointer. During the last few years, however, an inferior grade of labor has had to be employed, often unable to understand the instrument, and it has become necessary, therefore, to use some other means to indicate to the furnace operator when the temperature is correct or too high or too low.

In some plants this is done by signaling the temperature by lights from one central station. Three lights are grouped at each furnace: green, to indicate that the temperature is too low; white, correct; and red, too high. This system requires, however, the maintenance of a central operator to flash the signals and usually an elaborate switchboard and wiring system from the furnaces to the central station.

Recently, however, an instrument has been developed to operate the signal lights from a pyrometer automatically. In this instrument, whose construction is very similar to that of the ordinary indicating pyrometer, a contact table adjustable throughout the whole scale range carries three contacts corresponding to the three lights, the central contact operating the white light, usually covering a space of 20 deg. on the scale, amounting to 10 deg. above or below the desired temperature. The pointer on the

pyrometer is automatically depressed once a minute on the tungsten contacts.

An automatic three-position relay is operated by the closing of the contacts in the instrument. Let us assume that the furnace is started up and the low contact is closed, corresponding to the green light, and the relay complete the circuit through the green light. The contact in the instrument is only closed a few seconds to operate the relay, but the green light continues to burn until the temperature rises to the desired point, when the relay shifts, causing the white light to burn and extinguishing the green light. The proper light continues to burn at all times, although the contact in the instrument only closes for a few seconds once a minute. (*Journal of American Steel Treating Society*, vol. 1, no. 4, Jan. 1919, pp. 131-132, d)

## MOTOR-CAR ENGINEERING

**MOTOR SLED.** Description of a motor sled now being perfected by a company in Seattle, Wash.

The propelling force is obtained by applying the principle of the ship propeller to two revolving drums turning in opposite directions and having secured to them a series of spirals that force the sled ahead just as a bolt is forced through a nut when turning. The speed of the sled is changed by a special transmission through a conventional gear shift.

The fact that the propelling drums rotate in directions opposite to one another makes it necessary to employ a special gear drive. In this case it has three gears, the drive pinion from the engine directly meshing with only one of these gears. The lower two gears again mesh with one another and drive through separate shafts to centrally located sprockets and then through chains to the main-drive sprockets located in between the two drums.

Finally, the drums must be made perfectly cylindrical in shape in every transverse section and must be perfectly smooth.

It is claimed that there is absolutely no slip between the snow surface and sled.

In other words, for a given number of revolutions of the drum with a certain pitch of the skates, the actual travel is equal to the theoretical length of the travel.

The drums are made of pressed steel fastened by means of flanges and spiders to the drive shaft. The steel skates spirally located on the drum are of a very shallow depth—probably not over  $\frac{5}{8}$  in. high.

In addition to this, there are two vertical guides fastened on to the superstructure of the car, the object of which is to keep the drum shafts parallel in a vertical plane and also to allow the drums and drum shafts which are supported on a central pivot to oscillate around this point in order to conform to the road bed. (*Motor Age*, vol. 37, no. 12, Mar. 18, 1920, p. 30, 1 fig., d)

### Laxtonia Twin-Six Motor-Car Engine; Angle of "V" and Vibration of Engines

**BRITISH TWIN-SIX MOTOR-CAR ENGINE.** Description of the 12-cylinder touring-car engine designed by W. L. Adams of the Laxtonia Engineering Company, Peterborough, England.

The engine has several interesting features. The two blocks of six cylinders (Fig. 9) have an angle of 30 deg. between them. Such an arrangement is apt to increase vibration but makes the engine more compact, which, in this case, is further enhanced by the fact that the cylinder blocks are cast with the main portion of the crankcase as a single unit in aluminum.

The 30-deg. setting also simplifies the design as it enables a single overhead shaft midway between the two blocks to operate all the overhead valves, both inlet and exhaust, through the medium of rockers.

The crankshaft (Fig. 10) has only three throws and two journal bearings of the roller type. Two bearings are considered to be sufficient because the crankpins and journals are of  $2\frac{3}{4}$  in. diameter and the individual impulses are claimed to be of comparatively small magnitude.

A detachable cylinder head is fixed over each block of cylinders and carries the overhead valves. Each block of cylinders is staggered in relation to the other, to the extent of  $21/32$  in.,

FIG. 9 SECTION OF THE LAXTONIA 12-CYLINDER ENGINE

which allows the connecting rods of opposing pairs to lie side by side without their being offset in relation to the piston centers.

The overhead camshaft formed in one piece with its 24 cams

FIG. 10 CRANKSHAFT OF THE LAXTONIA 12-CYLINDER ENGINE

is driven by a train of three spur pinions enclosed at the front of the engines and lies in a trough formed above the main casting. The oil pump delivers oil through the branch pipe to this trough and the rotating cams serve to distribute lubricant to all the overhead gear, which is enclosed by a detachable aluminum cover.

While the engine has a capacity of 6900 cu. cm. (421 cu. in.) the two cylinder blocks are but 12 in. overall.

While it is admitted that the uniformity of turning effort in this engine falls below that of a 60-deg. twelve, its torque curve approaches that of the 12-cylinder Liberty engine, which has its cylinder blocks set at an included angle of 45 deg. There are two peaks in the torque curve of every 120 deg. of crankshaft revolution, the minor peak occurring 30 deg. in advance of the main peak. (*The Engineer*, vol. 129, no. 3349, March 5, 1920, pp. 252-254, 4 figs., d').

## POWER PLANTS

### Principles of Standardization of Power Plants; Suggested Types of Standard Units

STANDARDIZATION OF POWER PLANTS, Louis R. Lee. Standardization is recommended in the interests of plant efficiency, which the author defines as the ratio of the gross input to the gross output. The gross output may be expressed in pounds of steam or in kilowatt-hours. In the first case the efficiency ratio should

be effected only when they will not reduce the possible saving in operation and maintenance.

Fig. 11 shows several types of assembly of the complete unit and the different possible building arrangements. In *B* the plant shows the boilers, economizers and auxiliaries are housed in the main building, while the induced-draft equipment, coal bunkers and ash discharge are outdoors.

In *C* and *D* a reduction in size of the main building is secured by providing each economizer unit with a self-containing waterproof covering, this covering also extending over the aisles between economizers.

It is claimed that a comparison of any of these building arrangements with the best present-day practices will show much saving in cubical contents of the building when compared on a rate of horsepower basis. There is also a great saving in material for supporting equipment particularly the economizers and draft equipment.

The standard unit as designed by the author consists of a cross-drum boiler set singly with suitable stoker furnace and provided with a direct-connected economizer. The draft equipment consists of a forced-draft fan and an induced-draft fan, both motor-

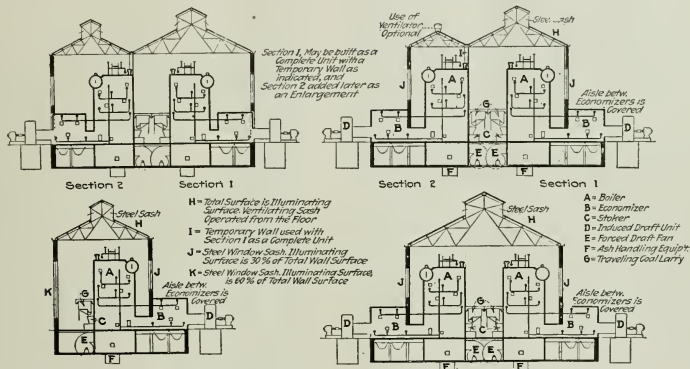

FIG. 11 SECTIONAL VIEWS OF SOME STANDARDIZED BOILER PLANTS AS DESIGNED BY LOUIS R. LEE. UPPER LEFT, *B*; LOWER LEFT, *C*; UPPER RIGHT, *D*; LOWER RIGHT, *E*

show the cost per thousand pounds of steam and in the latter case per kilowatt-hour, the cost of input covering all that is actually put into the plant, including cost of fuel, labor for operating, labor for maintenance and fixed charges on the total investment.

One of the most essential parts of all power plants is the boiler plant. The boiler complete with furnace draft equipment and feedwater supply is essentially a complete plant and it is only necessary to multiply the output of such a unit to secure any desired output. By making the unit a complete fractional part of a plant extensions are taken care of with minimum trouble and cost.

To make estimating of the cost of the installation easier and also to effect savings the author recommends devising the unit design with the limited selection of characteristic equipment bearing in mind the effect that the price of the fuel has on the installation.

Unless necessitated by local conditions such as occur in congested city districts, it is recommended in the design to use more ground area rather than high elevation. To secure low operating cost all equipment must be so located that all parts are quickly accessible and the disassembly is easily effected for making repairs and maintenance. Savings in first cost of construction must

be effected only when they will not reduce the possible saving in operation and maintenance.

A central observing and controlling station is provided at each side of the boiler unit, these stations being arranged where desired, right and left hand, so that one operator may observe and control two units. Data as to the equipment and details of the apparatus used are also given. (*Power*, vol. 51, no. 10, Mar. 9, 1920, pp. 375-378, 2 figs., *gd*)

## CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

# ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

## A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulae or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

**Apparatus and Instruments 45-20 Accuracy of Chronographs.** The use of photographic records to determine the uniformity of motion of clockwork used to drive recording mechanism and to determine the uniformity of chronographs has been developed by the Bureau of Standards. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Apparatus and Instruments 46-20 Anemometer.** An air-speed indicator of the Robinson cup type with centrifugal indicating mechanism has been calibrated. This instrument is of German manufacture and is very compact and well adapted for use on dirigibles. It is independent of changes in air density and gives actual air speeds. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Apparatus and Instruments 47-20 The Leucoscope Used in Pyrometry.** The Bureau of Standards has found that the leucoscope of Helmholtz is applicable to pyrometry and spectral energy distribution in a light source or furnace. These data have been communicated to the Optical Society of America and will appear in its Journal. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Apparatus and Instruments 48-20 New Instrument for Measuring Small Air Velocities.** Thesis by A. E. Reinhard and J. R. Cain, Rose Polytechnic Institute. Use of the standard pitot tube with instrument for measuring the difference of pressures.

Two shallow, airtight tin boxes about 6½ in. square have square openings about 6¼ in. on a side cut in the tops. Within each opening a square aluminum plate, 5½ in. on a side, is located so as to be central and in the plane of the top of the box. Thin gold leaf is then cemented to the aluminum plate and to the top of the box so as to make an airtight receptacle with a flexible top.

A suitable wooden base is provided with a column for supporting an equal-arm balance, which is sensitive to one grain. The air boxes are fastened to the base so that the centers of the boxes are vertically below the respective ends of the balance lever, and the aluminum plates are connected by suitable cords with the arms of the balance. Suitable stops are also provided for limiting the movement of the diaphragm so as to prevent tearing the gold leaf.

When the air boxes are connected respectively to the dynamic and the static sides of the pitot tube, the net effect upon the balance is due to the pressure equivalent of the air velocity which is being measured. The scales are first balanced with both air boxes open to atmosphere. Then connections are made to the pitot tube and weights added until a balance is again obtained. The added weight divided by the effective area of the diaphragm gives an absolute measure of the difference of pressure.

The instrument was found to be sensitive enough to record a velocity of 1½ ft. per sec. At 3 ft. per sec. the probable error was about 3 per cent. This instrument is not suited to high velocities. It was used successfully to measure velocities between 1½ and 15 ft. per sec.

Address Prof. F. C. Wagner, Rose Polytechnic Institute, Terre Haute, Ind.

**Internal-Combustion Motors 42-20 Monel Metal for Engine Valves.** The Bureau of Standards has recently used exhaust valves made of monel metal in a 180-hp. Hispano-Suiza engine during 130 hr. of running time. The tests were of 6 hr. duration. During this period 90 hr. of the test were devoted to the study of lubricating oils while the engine ran at 1800 r.p.m. and developed 130 to 140 hp. At the end of 45 hr. the valves were found to be badly pitted and the valve seats were found to be in the same condition. During the next 45 hr. the power was the same as before and after this the valves were opened for 40 hr. service under severe conditions while the engine was used to study pre-ignition. High temperatures were experienced and the electrodes of the spark plugs were fused, the melting point being in the neighborhood of 1500 deg. cent. In spite of this severe test the

valves seemed to hold up as there was no drop in power. The valves were found to remain red for nearly a minute after the valves in the other cylinders had become black.

The pitted appearance of the valves does not seem to affect the gas tightness. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

**Chemistry, Organic 41-20 Camphor.** A new step in the process of manufacture of synthetic camphor from pinene (turpentine) has been studied by the Institute of Industrial Research. Camphor is a necessary constituent in the manufacture of celluloid and allied compositions, and is used in the manufacture of moving-picture films. Up to the present time camphor has been almost exclusively Japanese monopoly. Institute of Industrial Research, 1845 B. St., N. W., Washington, D. C. Address Allerton S. Cushman, Director.
